Local Health Administration and General Health Questions: Bailie P. J. Dollan, Glasgow; Mr. A. Findlay, Aberdeen; Mr. Hugh Fraser, Inverness; Bailie Simon G. Fraser, Dundee; and Mr. M. A. Reynard, Clerk to the Glasgow Parish Council.

Highlands and Islands: Mr. J. G. MacDonald, Inverness, and Mr. Hugh Miller, Stornoway.

Welfare of the Blind in Scotland

The second report of the Scottish Advisory Committee on the Welfare of the Blind was issued last week.[1] The report, which covers the period 1921-24, is signed by Sir David Paulin (Chairman) and Sir William Reid (Vice-Chairman) on behalf of the committee, which includes representatives of public authorities, voluntary agencies and blind workers. The medical profession is represented by Dr. George Mackay, consulting ophthalmic surgeon to the Edinburgh Royal Infirmary. This committee was set up shortly after the passing of the Blind Persons Act, 1920, to advise the Scottish Board of Health on the care and supervision of the blind in Scotland. As practical

[1] H.M. Stationery Office, 120, George Street, Edinburgh (price 1s.).

every question of importance affecting the interests of blind persons has been before the committee, the report is in effect a review of the problem of the care of the blind in Scotland and an account of what is already being done. There are, the report states, 6 054 blind persons in Scotland on the Central Register kept by the Board of Health. The gradual increase in the number of blind persons registered is attributed to the greater interest in the blind since Government grants were provided for voluntary agencies and the responsibility for the welfare of the blind was placed on local authorities. Of the total number of registered blind, 399 are under 16 years of age and 3,627 are over 50, 3,650 blind persons are unemployable. The committee records with pleasure the striking decrease in the number of blind children under 5 years of age—from 48 in 1920 to 15 on April 1st, 1924.

It may be assumed that this is to some extent due to the energetic measures that are being taken generally by public health local authorities to secure the prompt notification and treatment of cases of ophthalmia neonatorum and also for the systematic and effective treatment of persons suffering from venereal diseases.

The report discusses and makes recommendations on the education and technical training of the blind, the wages of blind workers, municipalization of workshops, the disposal of goods made by the blind, home work, home teachers (their training and qualifications), residential homes, the medical certification of blind persons, and methods of dealing with those who are incapable of working or being trained. Many of the recommendations of the committee have been adopted by the Board of Health and are now the accepted policy in Scotland. The committee, by a majority, agreed to recommend that as a general principle the municipalization of workshops for the blind is not at present desirable. The committee disapproves of the Blind Persons Act (1920) Amendment Bill, as drafted, which is at present before Parliament, and an alternative scheme of amending legislation is substituted as a "substantial solution of the whole problem of the blind." In the committee's opinion blind workers in institutions are already substantially provided for and new legislation must deal principally with the problem of the unemployable and necessitous blind. It recommends that a graduated compensation allowance of not less than £1 a week should be granted to blind persons within a prescribed means limit, and that this should be paid to the capable and incapable blind alike, two-thirds of the cost of the compensation allowance being met by the State and one third by the local authorities. It recommends also that power should be taken to provide that the standard minimum wage to blind workshop employees should be not less than that paid to unskilled municipal workers in the district, on condition that the recipients should be qualified workshop employees who have undergone a course of technical training and are capable of earning a reasonable wage. The other recommendations deal with the granting of powers to local authorities in Scotland to promote arrangements for the prevention of blindness, the necessity for the approval of the Scottish Board of Health to the registration of charities for the blind, and the empowering of the Board to compel local authorities to combine where necessary for the purposes of the Act, and also to compel local authorities to enforce the provisions of the Act.

Edinburgh Royal Infirmary

At a meeting of the board of managers of the Royal Infirmary on October 6th, Lord Provost Sir W. L. Sleigh presiding, several vacancies on the visiting staff were filled up. Dr. Andrew Rutherford was appointed assistant physician. Messrs. J. J. M. Shaw and F. Gordon Bell were appointed assistant surgeons. Dr. Robert Aitken was appointed assistant physician for diseases of the skin. Dr. James Young was reappointed assistant gynaecologist. It was stated that 1 482 patients had been treated during the past two weeks in the institution and 1,796 new cases had been treated in the out patient department. The number of cases awaiting admission to the infirmary on October 1st was 1,684.

Glasgow Post-Graduate Courses

The Glasgow Post Graduate Medical Association has arranged a series of weekly demonstrations for medical practitioners in the various hospitals of Glasgow commencing on November 5th and continuing until March 27th, 1925. Some short special courses will also be conducted. Further particulars can be obtained from the secretary of the association, the University, Glasgow.

West of Scotland Foreign Service Medical Club

The West of Scotland Foreign Service Medical Club consists of medical men who served overseas during the great war, all its members we are glad to know, are also members of the British Medical Association. The sixth annual meeting and dinner of the club will be held in the Grosvenor Restaurant, Gordon Street, Glasgow, on the evening of Tuesday, October 28th. The honorary secretary is Dr. David Shannon, 26, Woodside Place, Charing Cross, Glasgow, C.3.

Ireland.

The Royal Academy of Medicine

During the session of 1923-24 the Royal Academy of Medicine in Ireland consisted of 193 Fellows, 13 members, and 26 student associates, an increase of 20 Fellows and 6 members over the previous year. The accounts for the session have been audited, and the financial state of the Academy is shown in the balance sheet appended to the annual report. The total income for the year, including a balance of £40 carried forward from the previous year, amounted to £483, and the expenditure to £407. By the kindness of M. Blanc, the French Consul, a cinematograph film illustrating events in the life of Louis Pasteur was lent to the Academy, and on December 11th 1923 the Academy entertained a large number of visitors to view this interesting film on the first occasion that it was shown in Ireland. The council records with deep sorrow the deaths during the session of three honoured Fellows of the Academy, Wallace Beatty, Alexander O'Sullivan, and Sir Andrew Horne. The urgent need for the provision of facilities in Dublin for research in connexion with medicine and the allied sciences was brought before the council and a conference of the various licensing corporations in Ireland was invited to meet the members to discuss the matter. At that conference a scheme for the establishment of a research institute was drafted, and the draft has been submitted to the various corporations which were represented. As soon as the approval of these bodies has been received it is proposed to submit the scheme to the Government. The council has good grounds for believing that the scheme will be adopted, and hopes that in the next report it will be possible to speak of the actual establishment of the institute. During the session there were 27 sectional meetings of the Academy at which the attendances were: Fellows 637, members 55, associates 161, and visitors 338, or a total of 1 191, as compared with a total of 941 in the previous session. The plan of holding a combined meeting of the sections of medicine and surgery was again adopted during the year, and on January 25th Mr. D. P. D. Wilkie of Edinburgh opened an interesting discussion on "Jaundice." This meeting was well attended. On February 29th Mr. James Sherren of London read a paper before the surgical section on "Diseases of the stomach and its surgical treatment." The paper evoked great interest among the 100 persons who were present at the meeting. On May 5th Sir Leonard Rogers, F.R.S., by invitation of the council, read a paper before a special meeting of the Academy on "L. proteus, its cultural characters and its relation to tuberculosis."

Health of Belfast

Dr. Baillie, the Medical Officer of Health of Belfast, has just issued his annual report for 1923. It is especially interesting because in that year the mortality was the lowest on record, and because it includes the first report of the School Medical Service. As no census was taken this decennium, the

figure for the population is an unreliable estimate after fourteen years from an actual count, and so all figures calculated from the population are more subject to error than if only a few years had elapsed The death rate for 1922 was calculated at 14 8 per 1,000, that for 1923 at 13 8—the actual number of deaths being 7,117 The births numbered 10,426, or 25 0 per 1,000 in a population of 429,000 as estimated by the Registrar-General Only 4 deaths were caused by typhoid, but 308 were due to measles and whooping cough A decrease of 0 2 per 1,000 in deaths due to phthisis is also very satisfactory, considering the steady fall during the last twenty years When one considers the mortality rates of the last decennium of last century there is every cause for sincere congratulation

Belfast School Medical Service

The first annual report of Dr T F S Fulton, chief school medical officer, is published with Dr Baillie's report, and gives a survey of the work of the School Medical Service under the new authority During the year 76,700 inspections were made, and the service appears on the whole to have won the approval of the parents The poor condition of the schools had from time to time met with serious criticism The late Dr Alex McKeown had drawn attention to the wretched state of some of the buildings, Professor Lindsay had again and again tried hard to arouse public indignation, others, too, had joined The disgraceful condition was known to the health authorities, and they did what was possible for them, but they were not the body responsible It is curious that in a city where public protests were common, and many worthy enterprises for the public benefit were undertaken, no public movement as regards elementary school education was ever set on foot, or indeed mentioned, by any class, and the children were allowed to suffer in mind and body during the attempt to educate them Dealing with the general hygienic condition of the schools, the report states that of the 194 school buildings in Belfast, 53 are totally unsuitable for the purpose, 29 are graded as to be replaced as time serves, 100 are satisfactory, or can be made so, 11 are good The majority of the schools have insufficient ground space Complaint is made regarding the lighting and the ventilation, the old-fashioned type of desk, the insufficient room and floor space—100 children are cramped into floor space which normally should accommodate 30 to 50 In the private protests that were made earlier much stress was laid on deficient sanitary accommodation, but it is understood that this came under the control of the public health authorities, and was remedied With a regular medical service and a new authority, every hope is now entertained that the children will have their bodies as well as their minds properly looked after The old accusations have been fully substantiated

Correspondence.

POSTERIOR GRAVITY DRAINAGE IN EMPYEMA

SIR,—I should be much obliged if you would kindly allow me to supplement my article, on posterior gravity drainage in empyema, published in the BRITISH MEDICAL JOURNAL, May 5th, 1923 (p 758), by stating that the further experience of my colleagues and myself confirms the opinion therein expressed—namely, that posterior drainage invariably effects prompt cure We find, however, that taking as centre of external incision the termination of the two-and-a-half inch line drawn downwards from the inferior angle of the scapula occasionally admits of undesirable elasticity in way of encroachment on the posterior axillary line consequently, in order to secure free dependent drainage with immediate cessation of purulent secretion and rapid cicatrization of sinus, thoracotomy (with or without excision of a piece of the ninth or tenth rib) should be executed just posterior to the posterior scapular line—a point which can be rapidly determined by counting the ribs from below upwards in the said line

Again, I wish to invite attention to the aseptic and excellent drainage afforded by the use of a wisp of silkworm gut in these and similar cases As elsewhere stated, these wisps are made by doubling twenty to forty strands of silkworm gut and tying the double with a piece of silk about one half-inch from each end Permanent outdoor treatment is highly beneficial after operation—I am, etc,

Buenos Aires, Sept 6th JOHN O'CONOR, K B E, M D

TRAINING OF NURSES IN COTTAGE HOSPITALS

SIR,—At the Annual Representative Meeting at Portsmouth it was decided that the British Medical Association should support a proposal that nurses should be allowed to undertake part of their training for registration in cottage hospitals It may interest members to know that the Royal United Hospital, Bath, applied to the General Nursing Council for approval of the following scheme, under which probationers in cottage hospitals should be able to take up while there the preliminary examination of the General Nursing Council, and under which two years' work in one of these hospitals may count as one of the three required for registration

Scheme for the Training of Nurses in Cottage Hospitals in parts of Wilts and Somerset, under Section 1 (Clause 2) of the Scheme of the General Nursing Council

1 For the purpose of this scheme, such approved cottage hospitals as shall enter into it shall be affiliated with the Royal United Hospital, Bath Only such cottage hospitals as are approved by the General Nursing Council can be admitted to the scheme

2 Probationers of these hospitals shall, during the first four months, undergo at the cottage hospital the course of instruction set out in Sections 1, 2, 4, and 5 of the syllabus for the first year of training

3 During the following twenty months they shall attend lectures given by the Sister Tutor at the Royal United Hospital Bath These lectures shall be given at that hospital or at such cottage hospitals and at such times as shall be most convenient for the attendance of the probationers

4 At the end of this two years' training and lectures a probationer shall be qualified to enter for the preliminary examination, and the two years thus occupied shall, for the purposes of registration be considered equivalent to one year in a complete training school

5 There shall be an undertaking on behalf of the probationer that after passing her preliminary examination she shall carry out the third and fourth years of her training at the Royal United Hospital, Bath, or at some other recognized training school for nurses This undertaking shall not apply in the case of those nurses who intend to train as midwives only

This scheme has been approved by the General Nursing Council In order to arrange details as to the places where and the times at which the lectures will be given, and the payment of expenses, it will be necessary to hold a meeting of the matrons or other representatives of the hospitals concerned The council has approved the following hospitals Chippenham, Frome, Melksham, Paulton, Saverake, Shepton Mallett, Swindon Victoria, Trowbridge, Warminster—I am, etc,

Bradford on Avon CHARLES E S FLEMMING

OBSTETRICS AND LOCAL HEALTH AUTHORITIES

SIR,—I write to express agreement with Professor Louise McIlroy's letter on the above subject, which appeared in your issue of October 4th (p 642)

After sixteen years of medical practice, ten of which have been spent in the public health service, I would add my testimony as to the results of unskilled midwifery in producing the chronic ill health of many mothers who attend child welfare clinics, and a certain number of the cases of paralysis, sometimes accompanied by mental defect, which occur among school children

One of the means by which an attempt is being made at betterment is the ante-natal clinic Such a clinic is more effective if the medical officer in charge, whether whole or part-time, is not only possessed of previous experience in gynæcology and obstetrics, but continues to maintain practical touch with them This is to some extent the case in areas where the ante-natal medical officer is also in charge of the maternity home and wards to which cases are admitted under the local authorities' maternity and child welfare scheme

Dr McIlroy suggests that one all-time medical officer might carry out the combined duties of ante-natal medical officer, emergency obstetrician to the local midwives, and inspector of the latter This suggestion has much to commend it, and would have still more if charge of the local

maternity home were added to the duties One obvious advantage would be the closer co-operation between the practising midwives and the ante natal centres, which is so desirable and still so absent from many areas

If Dr McIlroy's suggestion should appear to savour too much of municipal midwifery for those of your readers who object to this line of medical evolution, there is the alternative one of a local obstetrician of recognized standing who would be willing to act as the emergency consultant for the local midwives, and to take part-time service under the local authority as medical officer to their ante natal clinics Such an officer would be in regular, not occasional, attendance at the clinic, and would co-operate with the inspector of midwives for the district

The separation of the ante natal from the infant welfare work, which usually have been combined under one officer, may also be objected to by some, but obstetrics is a branch of medicine for which many doctors of both sexes have neither liking nor natural aptitude, and for one who will make a successful obstetrician there will probably be several potential infant welfare specialists It is therefore open to doubt whether the prevailing arrangement although convenient, is the one best calculated to achieve results

As regards nursing mothers, it will always be more natural and convenient for the mother of a young baby to attend a clinic with her baby and have supervision of her general health and diet from the medical officer in charge of the latter, but she could attend a so-constituted ante natal clinic at least once within a few weeks of her confinement, and be subsequently referred to it whenever any condition arose suggesting the necessity for further consultation, and her special needs could thus be met without the establishment of another special clinic —I am, etc,

Willesden Oct 6th AGNES HILL NICOLL

SIR,—Dr McIlroy's letter in your issue of October 4th (p 642) seems to me to raise some curious points for the consideration of the general practitioner Her suggestions, as far as I understand them, amount to the following That no general practitioner should be allowed to attend an abnormal confinement if he does not hold a special permit from some competent authority That he may be allowed to do so when the medical inspector or those holding permits are not available

I should like to know if Dr McIlroy seriously suggests that when a practitioner has attended a confinement at the request of a midwife he should be compelled to furnish a detailed report of his treatment to the medical officer of health? Finally, what about the patient? Perhaps she would prefer some ordinary practitioner (who has no permit) rather than the medical inspector provided —I am, etc,

Liverpool Oct 6th. C A ROBINSON

HOSPITAL TREATMENT OF EARLY MENTAL DISEASE

SIR,—In an article in your issue of September 27th Dr Comrie brought before us the results of the treatment of early mental illness in the wards of the Edinburgh Royal Infirmary The fact that 72 per cent of 500 cases in the course of one year were discharged sufficiently well to return home speaks for itself and Dr Comrie is to be congratulated Surely the day is not far distant when all general hospitals will set aside beds for the treatment of mental disease in its incipient stages

There is one point, however in Dr Comrie's paper that requires some elucidation What does he mean when he says, referring to the psycho neuroses that a previous sexual trauma in the Freudian sense was found to be especially prevalent? I am unaware that Freud places especial significance on the presence of a sexual trauma in the life-history of his patients The roots of a psycho-neuro is are to be found deeply imbedded in the patient's unconscious mind, and can only be found after prolonged analysis

Again, Dr Comrie says 'In my opinion, however, the employment of this procedure [psycho-analysis], while very useful in elucidating the vagaries of the patient, is more apt, considered as a therapeutic agent, to be followed by increased mental unrest and distress than by improvement" Dr Comrie cannot be referring to the psycho-analysis of the cases under review, for it is obviously impossible to analyse thirty five cases in fifty-four weeks If he means the investigation of the patient's sexual life by cross-examination I am in full agreement with him, but this is not psycho-analysis in its Freudian connotation, and Freud himself has warned physician against the dangers of such pseudo-analysis —I am, etc

Dunfermline Oct 6th DAVID MATTHEW, M B, D P M

SIR,—The account given by Dr J D Comrie in your issue of September 27th of the Hospital treatment of early mental disorder is interesting One would like to know whether the entrance of the patient was altogether voluntary and whether he was detained or could leave if he chose It might, perhaps, be suggested that a more satisfactory arrangement than the grouping of so many varieties (epileptics inebriates, defective, and toxic cases—many of them requiring quite distinctive treatment) might be arrived at by the starting of specialized home, colonies or places adapted for the care of delirious cases—for example puerperal or influenzal It is desirable that the latter should in every instance be kept apart from the stigma associated with lunacy

Dr Comrie stresses the fact that many of his cases were directly attributable to the vicissitudes of life We may almost venture to say that in the majority of such there is no disease at all He states It is important to note that most of the attempts at suicide were made by persons suffering from simple melancholia without delusions" What is most needed in all early mental cases is reassurance and hope for the troubled mind, and the supply of new interests to which mental activity may be directed The atmosphere of a general hospital can scarcely be said to be an ideal environment for furnishing these essential In his cases recovered enclosed within hospital walls in the midst of a great city how much sooner would their balance have been regained with direct access of open air and sunshine and less concentration on their own ills and those of others The great need for multitudes of such cases is not for more hospitals but for homes or health and rest specially adapted for the recovery of mind and body

No legislation is required for the purpose of carrying out this greatly needed development There exists at present no legal barrier to the running of hospitals or homes for those not dangerous and unfit to be at large—in other words, the uncertifiable Dr Comrie states that in 64 per cent of his cases certification was unnecessary All that is requisite for the provision of the form of treatment here indicated is that Government grants should be extended to the health committees (as distinct from the asylum committees) of local authorities They already possess the powers needed to run homes of this nature—quite apart from lunacy and free from detention—which could be inspected and controlled by the Ministry of Health with a view to the prevention of illegal restraints or ill treatment

The most important advances in recent medical progress have been based on reasonable common sense applied to the prevention of disease or disorder It is well worth while to apply the same to the beginnings of loss of mental balance The slight increase in initial expenditure would lead in the end to a great saving and is likely to meet with an abundant reward —I am etc,

Dalry El Oct 11 S E WHITE

CANCER IN AFRICAN NATIVES

SIR,—For more than twenty years one has heard the statement has been made that malignant disease does not occur amongst primitive race Dr J Bell Walker of Aberdeen Scotland, recently wrote to me for details of a case of cancer that we had together in 1904 in a native Banyan man of Nyasaland which he thinks is the first recorded in scientifically proved I believe that the medical officer (of Chiromo) who must have the credit of first detecting was a Captain Fox He sent up to me as principal medical officer at Zomba a letter for consultation I agreed that it was an epithelioma and asked Dr J B Walker, then in charge of the Livingstone Memorial Hospital, to remove it I believe that he agreed with me and operated I then sent the specimen to the Imperial Cancer Research Fund, London, and, so far as I recollect heard no

more about it Dr Walker has now ascertained that the Fund staff put the specimen in their museum and forgot to examine it critically Dr J A Murray has had microscopical sections prepared, and the evidence entirely clinches our clinical diagnosis I had not heard of any cases in other doctors' hands, but since that mentioned above I have had three others of malignant diseases one a sarcoma of the parietal bone of the skull in a young native boy (a Chikunda), about twenty years ago, that quickly ended fatally, one of a sarcoma of the forearm in a Manganja woman, the third of epithelioma (cancer) of the tongue of a Yao woman Both women refused operation, and I left their district without being able to follow the cases to their termination

I think that cancerous diseases must be as ancient as *most others*, and that *some causes* that have usually been advanced, such as dietetic ones, have only a nutritional effect on embryonic cells that may predispose to growths Boys get warts on their fingers, possibly from seeing them on another boy's hands In 1900, north of Lake Nyasa, I was asked to see an official's native servant man who had been hypnotized by a native doctor called Mwakatundu It was 2 p m , and he could not be roused The old man certainly had an uncanny appearance, and ways likely to assist suggestion The above-mentioned case of a malignant sarcoma of the forearm I treated by suggestion for a few days, telling the patient to carry on the auto-suggestion treatment in her village That would be about 1912 When I returned to the district—I believe after a few months' absence—she was well and cheerful, and her tumour was only half the size that it was when she came to me

I have read of consecutive cases of cancer occurring in families or old houses, and such cause suggested as dry-rot in old flooring boards I advance the explanation that all cases may possibly be attributable to auto-suggestion as the causal exciting factor The power of concentrated thought, and especially the subtlety of the "unconscious," are known Animals have their subconscious mind, so why should not such an experiment as applications of the irritant tar to a guinea-pig's skin, causing cancer, be merely due to that I have given up reading medical journals for a great many years, so do not know whether my suggestion regarding the possible cause of malignant diseases has been advanced by anybody else, or whether experiments on cause and treatment may have been carried out along those lines I have retired from medicine and follow the precarious occupation of growing that seductive weed *Nicotiana tabacum* (the "Fumes of Hell" of James II), and it will be apropos to recommend it as a palliative of cancerous symptoms I believe a West of England chemist once advanced a preparation of violet leaves for this purpose Tobacco seems to have many remedial virtues I have found it of much value as a fomentation in influenzal pneumonia of natives Applied as old, dark leaves, with the mid-rib removed, done up in thin gauze, a few leaves thick, dipped in hot water, and kept damp with hot wet cloths, and warm with wool, etc , for some hours, according to effect, it would first have a stimulating effect, followed by a sedative one, besides an antiseptic action on the secondary microbic manifestations in malignant diseases It might, then, well deserve its ancient French name of "herba regina" I will close with this motto "Let fools step in when the great (pure scientists and specialists) and money have failed"—I am, etc ,

Makungwa, Limbe P O , Nyasaland J E S OLD

CARBON MONOXIDE POISONING

SIR,—Some years ago a tall, strong-looking young man, of good complexion, came into my consulting room He had scarcely sat down when he volunteered the following information "Doctor, I cannot get the idea of suicide out of my mind" I inquired fully into the possible causes, and in response to some questions bearing upon the conditions under which he worked, he stated that, some little time before, a gas stove had been installed in his office As far as could be ascertained he considered it an efficient stove, it was clean, convenient, economical, labour-saving, and it thoroughly warmed the office Strictly speaking, if "fume" be defined as "smoke or steam from combustion or exhalation," this apparently admirable heating apparatus gave off no fumes, no gas stove can give off fumes in this sense, carbon monoxide being a colourless and also an odourless gas, it is always present if there be incomplete combustion of coal gas Further questioning elicited the fact that this stove had *no outlet—in other words*, it seemed that as there was no visible exhalation there was no need for a chimney to carry away the products of combustion The conditions were the same as with an imperfect chimney, but, of course, worse in degree I have rarely, if ever, found the chimney from a gas stove that had an upward draught all round the inlet, as the simple device of carrying a lighted taper or match all round the inlet easily proved The stove in this young man's office was removed, and in a very few weeks he returned, quite happy, to my consulting room, and stated that the *morbid idea of suicide with which he had* been obsessed had left his mind Whether or not he had ever trusted to a basin of water to counteract the baneful effects of a lethal gas, that delusion and snare had, fortunately, not been relied upon by him

Some years before this incident I was sent for to see three children, said to be very ill It was a poor home in a squalid street, like many streets that deface a *beautiful* residential town in England On entering their bedroom and going towards their bed—there was only *one bed* in the room—there was a sudden sensation as of an iron band being tightened round my forehead, my head was in the poison, the children, being lower down, were comparatively free from it A fine warm fire of coke was glowing splendidly The diagnosis was quickly made a down draught from an inefficient chimney had been causing the room to be invaded by copious amounts of carbon monoxide Extinction of the fire was followed by the speedy recovery of the three children

To what is the complexion of the modern professional baker due? At 5 o'clock one morning I was permitted, by the courtesy of the owner, to go over a small bakery which was generally admitted by the consumers of most wholesome-looking, pleasant-tasting bread, to be efficient It surprised me not a little to find that our bread was cooked in an atmosphere of carbon monoxide, the fuel used being coke, which was burned in the oven The cause of the ruined complexion of the workers was quite obvious This bakery, like many others, was "passed" *annually*, after an expert inspector's careful examination I would advise him to combine a little physiology with hygiene and sanitation The conditions under which the bread was cooked, however, raised two questions in my mind Is the partially charred crust of bread capable of absorbing large quantities of the poisonous monoxide—colourless, odourless, and tasteless—just as charcoal can absorb very many times its own bulk of many gases? And what is the physiological effect of consuming a foodstuff that has been cooked until part of it undergoes a modified charring—being "well fried," as is said—in an atmosphere of carbon monoxide? At present I am unable to answer these questions From clinical observation, however, I am convinced that the vitamine properties of bread so prepared are destroyed, and that the physique and health of the consumers—that is, a very large number of people—are, in an insidious way, very much impaired —I am, etc ,

Reston, Berwickshire R CUNNINGHAM AFFLECK

ASSISTANTS IN GENERAL PRACTICE

SIR,—I was interested to read the letter headed "The hours of medical work" in the JOURNAL of September 20th (*p* 542), and I heartily endorse the views expressed therein

The British Medical Association has done admirable work in obtaining a minimum scale of remuneration for assistant health officers When will the Association make a thorough investigation into the conditions of drudgery under which that huge number of underpaid, overworked, badly housed members of the profession—the assistants in general practices—live?

Surely an average remuneration of £350 per annum, and a working day of twelve hours with repeated and frequent night work, and with but one free afternoon a week—and often not even that—is a state of affairs that should not be permitted to exist?—I am, etc ,

September 21st EX-ASSISTANT

Obituary

W H A JACOBSON, M Ch Oxon, F R C S,

Consulting Surgeon to Guy's Hospital

We had to announce with much regret in our last issue the death on September 14th, at Lordine Court, Ewhurst near Hawkhurst, of Mr W H A Jacobson, M Ch, F R C S, consulting surgeon to Guy's Hospital

Walter Hamilton Acland Jacobson was born at Oxford in 1847 he was the second son of the Rev William Jacobson, then Public Orator of the University and Vice Principal of Magdalen Hall, soon afterwards Regius Professor of Divinity, and eighteen years later consecrated Bishop of Chester He was educated at Winchester and Corpus Christi College, Oxford, where he took a second class in Moderations and graduated with first class honours in Natural Science in 1869 Soon afterwards he entered Guy's Hospital Medical School took the M R C S in 1872 and became F R C S in 1875 Many years later, when the M Ch degree was established at Oxford, he felt it his duty to sit for this examination before he could conscientiously examine for it In the course of time he was appointed demonstrator of anatomy, assistant surgeon, and teacher of operative surgery at Guy's Hospital, and he rapidly developed into a wonderful teacher of anatomy and surgery He was assistant surgeon for over twenty years full surgeon for three and consulting surgeon for nearly twenty years He was also surgeon to the Royal Waterloo Hospital for Children and Women, Waterloo Road

W H A. Jacobson

Photograph by] [Speaight Ltd London

No man ever gave more devoted and loyal service to his medical school and hospital than Mr Jacobson His work at Guy's came before everything else During "take in" or when he was in Clinical" he was often in the wards by 7 a.m, even though he had been operating late at night He frequently walked to the hospital from Great Cumberland Place His lectures on anatomy were extremely popular because he had the gift of making the dry bones live" his apt surgical allusions showed the great importance of anatomy in practical surgery He prepared these and his surgical lectures with the greatest care and generally arrived a long time beforehand and covered several blackboards with beautifully written and accurate notes and excellent drawings He often distributed printed notes of his clinical lectures, which men treasured for many years His surgical lectures and demonstrations were crowded, for his brilliant intellect, extensive knowledge, fascinating personality, and scintillating wit and humour made everything he said interesting and memorable Men frequented his lectures, not only to gather sound knowledge and to be signed up," but also to obtain mental refreshment and stimulation Like the great teacher he was, he took pains to make everything clear to the dullest member of his class For twenty years his "Out-patients" were most instructive and amusing, they were packed with students to the last His kindness, sympathy and generosity to his hospital patients were so extraordinary that many of them walked long distances to see him and to show themselves years after they had completely recovered

His love for the students was deep and genuine he helped them in all sorts of ways, often without thought or any reward 'Pom's" personal ascendancy over his pupils was so remarkable that he could say what he liked to them He told them the blunt truth and exercised his ready wit and sarcasm upon them, but he never meant any harm by it The men realized that it was all for their good, and they loved and feared him in return, some of them were a little hurt because he was rude to them, thinking that he did not notice them, but 'Pom' knew full well that they did not need any special attention

Jacobson's boundless energy and great literary ability enabled him to write his unrivalled book *The Operations of Surgery* afflicted as he was for many years with severe insomnia, he made good use of the time it afforded him and did most of his writing after waking in the small hours of the morning This book was the outcome of a strong belief which he had held for many years that a work on operative surgery which aimed at being more comprehensive in scope and fuller in detail than those already published would be of service to many who had recently been elected to hospital appointments and to those who were working for the higher examination The first edition of this book appeared in 1888 and exceeded beyond all expectation for its wealth of clinical experience its accurate and critical descriptions of operations and its sound common sense made it indispensable to every surgeon It is probably the best book ever written on general operative surgery and has run through six editions the last of which appeared in 1915 Jacobson wrote another good book on *Diseases of the Male Generative Organs* published in 1893 and he revised several editions of John Hilton's great work on *Rest and Pain* His contributions to the *Guy's Hospital Reports* were numerous and valuable and lucid and charming in style He also wrote some of the best articles for Holmes's *System of Surgery* and for Heath's *Dictionary of Surgery* Through his writings Jacobson became known all over the world and many medical men came to see him and his work at Guy's Hospital It was a pity that he had to wait such a long time before getting his beds He was on the Court of Examiners of the Royal College of Surgeons for some years and he also examined for the University of Oxford

We are indebted to Mr P P Powlands surgeon to Guy's Hospital for the following personal tribute

When I first knew Jacobson over thirty years ago he was assistant surgeon and lecturer in anatomy and at the height of his fame and power He presented a distinguished and striking figure A little over middle age his hair was already white and scanty he was of medium height rather thin light and extraordinarily quick and active his step was peculiarly springy His forehead was high and very prominent his face was lean and expressive He was a great walker and believed in taking plenty of exercise to keep himself fit Above all Jacobson was a character and a genius for both had an innate capacity for hard work pains combined with great natural ability and all his work was very human and apparent fruit of conscious and eccentricities He was the hero of numerous stories which are still told where Guy's men foregather Stern austere in manner he appeared to be a martinet but in reality was a most genial and sympathetic soul Once a stranger misled by his distinguished appearance mistook him for a famous knight and asked "Are you

Sir ——?" "No, sir," was the reply, "just common clay" He had a great contempt for anything that sounded false or savoured of self-advertisement, but he was very quick to discover merit and scrupulous in giving credit for good work done In short, he was a man of unblemished character, high ideals, great attainments, and lovable personality, somewhat capricious in his temper, he was *not* always easy to understand Too honest to suffer fools gladly, he must have found his ready wit somewhat of a hindrance to him in his private consulting practice, with the result that he did not reap quite as well as he sowed But after all, although he was full of honest ambition, *Jacobson never did anything for gain*, but rather for good

Somewhat late in life he was happily married, but the tragic loss of his son and only child, who was accidentally drowned in 1905, cast a shadow over his later years and led to his complete retirement from the profession which he had adorned The rest of his life he spent at his country house at Ewhurst in Sussex, devoting himself to his wife, his garden, and his poor neighbours He was very good and kind to the children, and had a great and lasting influence over them On Sundays he taught them the Scriptures, with the aid of wonderful pictures, and immediately afterwards taught them how to shoot or play games They adored him in return and made his latter days happier Those who had the privilege of visiting him at Lordine Court can picture him still in his beloved garden, suitably but wonderfully clad, bending to his toil, proudly showing a rare and beautiful plant or bringing a weakling to a better place in the sunshine

An old pupil, house-surgeon, and friend, Dr John Fred Briscoe writes

The death of Mr W H A Jacobson creates in many of his old pupils feelings of sentimental respect and regard The son of the late Bishop of Chester, he brought to bear on his work a nobleness of character which was unique He possessed the highest sense of duty to the profession which he adorned Those who had the honour of being his house-surgeons regarded him as an exemplary teacher imbued with the faculty of personal inspiration None but those with similar temperamental qualities sought his disciplinary advice, but he exacted from them a complete return of their services, both in and out of hospital Mr Jacobson steered the course of not a few in the way in which their professional abilities best fitted them in their future careers And his thoughtfulness and thoroughness were the advantageous assets which he passed on to others He objected very strongly to irregular manners and particularly to the use of unparliamentary language In fact, being finished himself, he expected the same polish from those who served under him As surgeon to the Royal Waterloo Hospital for Children and Women he was instrumental in raising it to a higher standard of excellence than it had hitherto attained Following in the footsteps of John Hilton, he reproduced the work of that great surgeon, *Rest and Pain*, besides his own standard book on *Operations of Surgery* Not least, he was a disciple and admirer of Dr Hilton Fagge, author of *Principles and Practice of Medicine*, nephew of John Hilton and one of the hardest worked physicians Guy's ever had His resignation at Guy's Hospital was prematurely the outcome of a family calamity, which caused his complete retirement His was the motto *Dare Aude*

SIR CHARLES CAMERON, Bt, M D, M Ch, LL D,

Formerly Member of Parliament for Glasgow

We regret to announce the death of Sir Charles Cameron, Bt, on October 2nd, at Englefield Green, Surrey at the age of 83 For twenty-four out of twenty-six consecutive years he was one of the representatives of the city of Glasgow in Parliament, and during that period became one of the most active and prominent of the private members of the House of Commons

Charles Cameron was the son of John Cameron, a newspaper proprietor of Glasgow and Dublin He was born on December 18th, 1841, in Dublin, and was educated first at the Madras College, St Andrews, and later at the University of Dublin At Trinity College, Dublin, he was senior moderator and gold medallist in 1862, and gained first place in the final medical and surgical examinations of that year He graduated M A and M D in 1865 and received the degree of LL D in 1870 He continued his medical studies in Paris, Berlin, and Vienna Cameron's ample professional qualifications, however, did not lead him into the practice of medicine, for in 1864 he became editor of the *North British Daily Mail*, a Glasgow periodical of which his father was part proprietor During the ten years of his editorship he entered more and more into the public life of Glasgow, and by the beginning of the seventies his devotion to the cause of social reform, education, and temperance, and his interest in politics, had won for him a name among the more advanced members of the Liberal party in the West of Scotland In 1874 he stood for Parliament and was returned at the head of the poll for the undivided constituency of Glasgow, which at that time had three members When the city was split into separate constituencies, in 1885, he was again elected, and sat as member for the College Division for ten years In 1895 he lost that seat, but from 1897 to 1900 he represented the Bridgeton Division

During his many years of parliamentary life Charles Cameron had the distinction of getting no fewer than nine separate Acts placed on the Statute Book, and in recognition of his many services he was created a baronet in 1893 He was "the father of the sixpenny telegram", he introduced and carried the Inebriates Acts, also the Acts abolishing imprisonment for debt in Scotland, and the Acts conferring the municipal franchise on women in Scotland Other measures introduced by him secured various reforms in the Scottish Liquor Licensing Laws In 1893 he was made chairman of the Departmental Committee on the transit of cattle coastwise, in 1894 chairman of the Departmental Committee on habitual offenders, and in 1895 a member of the Royal Commission on Liquor Licensing Laws

Sir Charles Cameron was the author of many papers and pamphlets on social and political subjects, his occasional medical writings, as might be expected, were addressed rather to the public than to the profession, and dealt with such matters as vaccination and the prevention of cholera He was president of the Health Section of the Social Science Congress in 1881, and of the Public Health Section at the Annual Meeting of the British Medical Association held at Belfast in 1884 His presidential address at Belfast was entitled "The Cholera Microbe and how to Meet It," and was printed in full in the British Medical Journal of August 2nd, 1884, page 233 In it he gave a scholarly account of recent research into the habits and peculiarities of the cholera bacillus In view of the interest which the question was then exciting, especially in connexion with the criticisms of English observers on the researches of Robert Koch, the address was reprinted at the close of 1884 in the form of a shilling pamphlet Another medical distinction in which he took pride was the gold medal of the Dublin Pathological Society In 1895, when the break in his parliamentary career took place, he was presented with his portrait by a wide circle of friends and admirers in recognition of his high personal character and his services to the city of Glasgow He was for many years a justice of the peace, and in 1894 was appointed a deputy lieutenant of the county of the city of Glasgow

Sir Charles Cameron married twice He is survived by his second wife, one daughter, and a son, born in 1903, who succeeds to the baronetcy

HENRY GERVIS, M D, F R C P Lond,

Consulting Obstetric Physician, St Thomas's Hospital

Dr Henry Gervis, who died on September 25th, was born in 1837 at Tiverton, Devon He was the eldest son of Mr F Shorland Gervis, a medical practitioner of that town He was educated at Taunton School, and while there gave evidence of the mental capacity that afterwards distinguished him In the school prize list of Christmas, 1852, he is recorded as having won the first prizes in Hebrew, Greek, Latin, history, chemistry, and German He received his medical education at St Thomas's Hospital, and there continued his habit of prize winning, and ended his career as a student by gaining the Treasurer's medal He also

obtained a medical exhibition and gold medal for anatomy and physiology at the University of London After obtaining the M R C S diploma in 1858, he graduated M B Lond in 1860 and proceeded M D in the following year He became M R C P in 1862 and was elected F R C P in 1874 Dr Gervis became successively assistant obstetric physician, obstetric physician, lecturer on midwifery and diseases of women, and consulting obstetric physician to the hospital His connexion with St Thomas's began when the hospital was situated in St Thomas's Street, continued through its temporary sojourn in the old Surrey Gardens, and was completed in the present building on the banks of the Thames He commenced practice in St Thomas's Street, and rapidly built up an extensive connexion In 1879 he removed to 40, Harley Street, and there became widely known as a consultant in gynaecological cases His courtly presence and charm of manner, combined with his vast stores of knowledge and great practical experience, made his advice eagerly sought for in his own specialty, and endeared him to an ever increasing circle of patients The cares of his busy practice left him scant leisure for writing, and beyond some brief contributions to the medical press, he has left no permanent literary memorial of his work, but his painstaking and accurate method of teaching must have left its impress on many generations of medical students

In 1899 Dr Gervis retired from practice and went to live at Hillingdon Heath near Uxbridge There his energy found vent in much public work, and he became a magistrate for the county of Middlesex Eight years later he removed to Bath, where he continued to reside until his death At Bath he took a keen interest in the Royal Mineral Water Hospital, of which institution he became a vice-president, in the District Nurses Institute, the now defunct Bluecoat School, and many other charities He took a great interest in antiquarian research, and in the transactions of the Huguenot Society, being descended on his mother's side from a Huguenot family He was an enthusiastic and learned gardener

Dr Gervis married in 1860 Phoebe Louisa daughter of the late S K Pollard, Esq, of Taunton Mrs Gervis predeceased him in 1918, after fifty-eight years of an ideal married life He leaves one daughter and one son, Dr Henry Gervis of Brighton

---

Dr Edgar Reid, who died on September 19th aged 59, received his medical education at Guy's Hospital He obtained the qualifications M P C S, L P C P in 1894, and the greater part of his professional life was spent in Swansea, where he was honorary gynaecologist at the Swansea Hospital During the war he was in charge of the 33rd War Hospital at Cardiff Throughout his life he was an enthusiast in sport, in Rugby football he was the captain of the Guy's Hospital and Swansea teams, playing three-quarter for both He also won distinction as a batsman in cricket, and was captain of the Swansea XI several times In 1896 he took an active part in the formation of the Pennard Golf Club, and was both captain and secretary on one occasion he was the runner-up in the Welsh golf championship He leaves a widow and one daughter A colleague writes "Deliver us from mean hopes, from fear and favour, and grant that we here before Thee may finish what remains of our course without dishonour to ourselves or hurt to others" This final prayer at the graveside so truly expressed the outstanding attribute of the friend whom we accompanied to his last resting place No one who came in contact with Edgar Reid, even if only for a short period, could imagine him stooping to anything mean or failing in his obligations In his varied pursuits he gave of his very best As a consultant in gynaecology he gained great success in an extensive practice by his operative skill and kindliness, which won for him the confidence and respect of his patients and the whole hearted support of those who worked with him, doctors and nurses alike As an athlete he had outstanding ability, excelling in many branches of sport He was held in great admiration as an exponent and he was as much appreciated for his generosity as an opponent, quick to express admiration of the prowess of any who defeated him, and unstinted in his praise of the skill of those whom he overcame He was a sport man in the noblest sense of the word He never harboured a lurking grudge nor a dishonourable thought Death has robbed us of a loyal friend and a most lovable colleague "Every heart that has beat strong and cheerfully has left a hopeful impulse behind it in the world, and bettered the tradition of mankind"

Dr John Charles Harris died on September 21 at Ramsgate, where he had lived since his retirement from practice nineteen years ago He was born at Chipping Norton, and received his medical education at Westminster Hospital, taking the diplomas of M P C S Eng 1859 L M 1860, L S A 1861 For over forty five years he practised at Croydon He was almost 89 at the time of his death, but during the last twelve months had practically been confined to his bed The death of his wife four years ago proved a great blow to him In his younger days he was an excellent raconteur, within a few months of his death, too, he could always be roused, and would chuckle like a boy at tales of the Heythrop hounds at Chipping Norton, the Bicester and Whaddon Chase pack We are indebted to Dr Swindale of Ramsgate for these few notes

---

The well known Swedish clinician, Professor Frithiloff Lennmalm, has recently died at Stockholm, at the age of 66

Dr Tommaso de Amicis, the *doyen* of Italian dermatologists and formerly director of the clinic of dermatology and syphiligraphy at Naples, has recently died

---

Dr Charles Gopis a leading Brussels oto-rhino-laryngologist has recently died

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.) *Articulate, Westrand, London.*

MEDICAL SECRETARY, *Mediocera, Westrand, London.*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus, Dublin*, telephone 4737 Dublin) and of the Scottish Office, 6 Rutland Square, Edinburgh (telegrams *Astate, Edinburgh*, telephone 4361 Central).

QUERIES AND ANSWERS.

OBSTINATE CONSTIPATION IN A CHILD.

'MEDICO' asks for suggestions for further treatment in the following case. A boy aged 3 with a history of chronic constipation and recurrent rises of temperature. Prolapse of the rectum occurs at times. The child has been given two tablespoonfuls of liquid paraffin a day with the result that one stool has been passed every other day. He has also had occasional soap-and-water enemas. He has now been put on a mixture containing sodium sulphate, tincture of belladonna and infusion of senna three times a day with liquid paraffin twice a day, and cascara cordial one drachm at night. Abdominal massage is being used, but the bowels are still obstinate and prolapse recurs at times.

ELECTRIC LIGHTING AND HEATING.

"D.M.O." writes: At present I use electricity for lighting on the "flat rate" plan, and I am thinking of adopting it on the "Norwich" system for heating purposes as well. I should be glad to hear the experiences and results of one or two medical men who have tried this system in the house and surgery.

INCOME TAX.

Cash Receipts or Book Debts?

D.L." has retired after thirty years' work in practice. The local inspector of taxes insists that he is chargeable in respect of debts paid to him after retirement.

"An assessment on a practice for a particular financial year is in respect of the profits of the practice *for that year*. It is calculated on a three years' average and is usually based as regards the gross profits on cash receipts rather than on a detailed estimate of the actual of the year's bookings, the method being convenient and yielding, in the long run, the same result. It therefore follows that when tax has been paid on assessments for a number of years to say April 5th 1921, the liability has been accounted for in respect of precisely the same period, and where the practitioner has ceased to exercise his profession there is no valid legal ground for assessing him for subsequent periods in respect of profits which he has, in fact, ceased to earn.

F.K.M." has declined to supply particulars of his book debts, claiming to base his liability on cash receipts. The inspector of taxes has now arranged for estimated assessments in excess of the amount of liability returned.

"The position with regard to the cash receipts basis is that where a practice is in a normal condition the actual receipts year by year approximate to the value of the year's bookings. If the cash receipts basis is displaced the difficulty that immediately arises is to estimate the value of each outstanding book debt—notoriously both difficult and important in the case of a medical practice. The matter was discussed with a leading official at Somerset House at length (see our issue of November 15th 1921, SUPPLEMENT, p. 185) and it was understood that objection to the application of the cash receipts basis would not be taken by the Inland Revenue Department except in abnormal circumstances—for example in the case of a new practice. We suggest that our correspondent should call the local inspector's attention to this fact and ask him what facts he has in mind in treating such cases as abnormal.

Average War-time Concession.

P.O.N. understands that there was an income tax concession to doctors who served as medical officers in the army during the war by which they were allowed on resuming civil practice to treat their army service years as part of the average for assessment. As the pay was generally less than practice earnings the concession might be valuable. The inspector of taxes states that the concession applied only to non-practising officers.

"It is always difficult to speak definitely of a concession, but so far as our information goes the basis of the concession was a recognition that service in the forces was a peculiar form of employment and that as a result where an officer in the R.A.M.C. resigned his commission and took on his pre-war employment—for example as an assistant, he was allowed to average his army pay for the purpose of his civil assessment. We believe therefore that the inspector is correct in stating that the concession did not extend to the earnings of a practice, which technically are not profits of an employment."

Non-medical Profits.

D.C." has been requested by the inspector of taxes to give full details of the profits made by him in his dealings in stocks and shares and asks: "Must I pay income tax on these profits and how do I stand with regard to my losses?"

"Whether D.C. is liable depends on whether he can correctly be said to be dealing in stocks and shares. If he does more or less habitually buy shares with a view to reselling them he is distinguishable from the more ordinary man who buys for investment purposes and may or may not form the intention later of reselling at a profit. In the former case his profits are assessable in the year the result of his transaction is a gain in capital and it is not liable to tax. Assuming that liability attaches to the gains, it follows that relief is due in respect of the losses. Ordinarily this relief operates automatically—that is, the actual amount of liable profit for a year will be the sum of the profits on various successful transactions less the sum of the losses on unfortunate speculations.

LETTERS, NOTES, ETC.

THYMOL FOR THE THROAT.

DR. WILLIAM COPEMAN writes: In the issue of Dr. Paul Gerhardt's paper in the JOURNAL of October 4th he recommends and has administered with success aqueous solutions of thymol in alcohol as a local application in the treatment of throat infections. This seems most remarkable in view of the well-known toxicity of thymol in solution and the empirical and dangerous practice of the necessity for avoiding alcohol when carbolic acid, creosote or cajuput oil are used externally during asthma. I am reminded

given thymol for ankylostomiasis whilst practising in the tropics, but with a wholesome respect for the views of Manson and others (q v) Dr Gethen's suggestion is very risky, to say the least of it, and I warn others against adopting it

STORIES OF PEOPLE TURNING RAPIDLY BLUE

SEVERAL cases have recently been recorded in which the patient turned "blue," and the reports have been gathered together by enterprising reporters into paragraphs which might seem to suggest that the blueness was in each case due to a similar cause This is clearly not the case In a fatal case the medical evidence was to the effect that the cause of death could not be stated in the absence of a *post mortem* examination, it might, for instance, have been acute pneumonia, acute laryngeal oedema, vascular disturbance, pulmonary thrombosis or embolism, heart disease, rupture of an aneurysm, or apoplexy—for example, pontine haemorrhage In children a rabbit bone or other foreign body may set up acute laryngeal spasm, other cases may be examples of acute food toxinaemia In one case poison seems to have been suspected by the coroner Again a deep ebony may be caused by a combination of cyanosis and petechial haemorrhage resulting from toxinaemia One case was a steel worker, and in this instance the discoloration may have been due to gas poisoning True melanosis is a slow process, and the discoloration is rather a sepia brown tending to black, though a bluish tinge might be produced by the sepia or black pigment showing through layers of epidermis In all fatal cases of the kind a *post mortem* examination should undoubtedly be made, as correct determination of the cause of death is desirable from the statistical point of view

SUGAR AND MIGRAINE

DR H BAZETT (Torquay) writes Dr Thomas's letter (BRITISH MEDICAL JOURNAL, September 27th p 598) is interesting and suggestive, but with the complex human mechanism, does it not invariably turn out to be an error to ascribe any one set of symptoms to any one single material cause? May I add my experience to the solution of the problem? I found several of the very worst cases I was called to as a general practitioner occurring in early and late adult life, but dating from childhood, yield entirely to a prescription of the juice of half a lemon, unsweetened, in a tumbler of water, on an empty stomach, night and morning, for the remainder of life In one case, a male breaking of this habit twice in the three years I attended him, led to quick recurrence of the fortnightly attacks I found that in all cases I could get a history of ancestral gout

CONGENITAL PYLORIC STENOSIS IN TWINS

A GOOD example of the close similarity, as it were duplication, sometimes to be observed in twins is contained in two notes published recently of two pairs of twins suffering from congenital hypertrophic stenosis of the pylorus In one instance, reported by H Leslie Moore, both the infants were submitted to Rammstedt's operation (longitudinal incision of the thickened serosa and muscularis down to, but not through, the mucosa) at the age of 4 weeks, both died of respiratory paralysis six and eight days after the operation In the other instance, reported by Herbert H Davis of Omaha (*Journal of the American Medical Association* vol 83 p 686), Rammstedt's operation was performed at the age of 4 and 5 weeks respectively Both infants did well, and about a year later won first prize for twins at a baby show

RESPIRATORY CRISIS IN AN INFANT

DR M L BARST (London) writes that he was called by a midwife to a baby, born two hours previously after a normal labour The baby was somewhat premature (37–38 weeks), but was rather large At birth it cried lustily, but soon afterwards its breathing became very shallow, and the crying was replaced by a feeble crowing Dr Barst found the baby markedly cyanosed with very poor respiration He turned it head downwards when it began to cry well, but on being placed on a pillow the cyanosis returned This was repeated several times Prolonged artificial respiration and a hot bath failed to effect lasting improvement Finally the baby was given an injection of 3 minims of pituitary extract into the buttock The effect was instantaneous the cyanosis disappeared, the respiration became normal, and the quality and volume of the voice became satisfactory Four weeks later the baby was quite well

ABSCESS OF FRONTAL LOBE

DR H W BERNARD (Dublin) writes The case reported in the JOURNAL of October 4th (p 622) ought to be of interest to general practitioners and dental surgeons, since the primary cause of the cerebral abscess was possibly left canine tooth root trouble, with infection of the antrum, purulent catarrh of the turbinates, and nasal mucosa Septic phlebitis and infection of the left frontal sinus may have been present with necrosis of bone, or phlebitis extending to the frontal lobe Pyorrhoea, with its resultant toxaemia may bring about dangerous results, but the upper jaw stumps should, I think, be attended to first, especially long canine stumps, since they approach close to the floor of the antrum

GOAT'S BUTTER

FROM a paper contributed by Mr T Knowles and Mr J C Urquhart to the last meeting of the Society of Public Analysts it appears that owing to the increase in the number of her Is of goats in this country the amount of goat's milk butter now sold is larger than formerly They have made a number of analyses and find that the Polenske value varies from 4 9 to 8 7 This, if interpreted in the light of the usual standards of cow's butter, would erroneously be assumed to indicate adulteration

The Polenske value of a fat is a numerical expression indicative of the proportion of fatty acids which are volatile and insoluble in water When it exceeds the number peculiar to butter fat the excess is interpreted as an indication of admixture with a vegetable fat, such as coco nut oil The Polenske value of the fat of cow's butter is never above 3 An observed Polenske value higher than 3 in goat's butter has not the same significance as in the case of cow's butter Neglect of this fact would lead to an erroneous judgement of the purity of the sample

MECHANICS OF SUCKLING

DR T A MACGIBBON (Christchurch, New Zealand) writes In reply to Dr C J Aitken (July 12th, 1924, p 88) may I state that the tongue *does take part* in the act of suckling More than ten years ago I propounded, in a letter to Dr Logan Turner of Edinburgh, a theory as to the mechanism of suckling in its relation to the moulding of jaws This theory—it is hardly a theory—has been copied almost word for word in Dr McKenzie's book, 1920 edition, on *Diseases of the Ear and Throat* In suckling the orbicularis oris muscle grips the first curve of the breast where are the ampullae The milk is squeezed into the ducts of the teat, which, being erectile, is distended and elongated, and lies between the tongue and the hard palate The final action is compression of the ducts by the tongue against the hard palate and the ejection of the milk on to the posterior third of the tongue occurs just before suckling, and is done to drag the teat or nipple into the mouth, where it is grasped The buccinators, which are used forcibly in true suction, are only rendered tense to act as fixation points for the powerfully acting orbicularis Where the buccinator is used for suction, as in bottle fed babies, the extreme contraction compresses the delicate jaws and causes deformity This is one of the chief causes of jaw deformity

PARTURITION AT THE AGE OF 13

DR J T DOW writes At 6 30 one morning I was called to a confinement, of which I had no previous knowledge, at a remote farm I found a girl, aged 13 years and eight months, beside her on the bed was a fully developed male child, living, and with an evacuated afterbirth attached The vulva was much swollen and oedematous, and protruding from it was a large clot The uterus was well contracted, gentle pressure expelled the clot and controlled the haemorrhage The appearance of the external genitals was then extraordinary, just a trickling of blood from an aperture, the diameter of an ordinary pen, in the surrounding swollen mass Birth had obviously taken place at least one hour before The pulse was 110 and the patient had a moderate degree of shock The history of the parturition was pitiful she had come home from the village school in pain forty hours previously and had lain in bed unattended and terrified till my arrival, ignorant of her pregnancy and the reason for her pain I had her transferred at once to the local Poor Law Institution, there, under care and kindness, her mental state improved There was no perineal tear, but some intravaginal sloughing She and her baby, we glhing 6 lb, are recovering normally, and are yet another instance of the wonderful care of Mother Nature

PNEUMOCOCCAL POLYARTHRITIS

DR T GERALD GARRY (Cairo) writes with reference to Dr Gubb's paper Cases similar to that he describes were very frequent as a sequel to bacillary dysentery (from which apparently his patient suffered) among soldiers in the Near East during the war, and generally recovered under appropriate antidysenteric treatment, without ever ending—in uncomplicated cases—in suppuration I think it extremely probable that examination of the faeces would have cleared up some doubtful points, and that to the "numerous pneumococci" could not be attributed the *jons et origo* of the malady

WHISKY AND CANCER

DR JAMES JEFFARDS, (Kegworth, Derby), writes Malignant disease being very prevalent in my district, many cases have come under my care in twenty five years of general practice During this time I cannot recollect one case occurring where the subject was a whisky drinker, in beer drinkers occasionally, but the majority of cases occurred in people who were either total abstainers or very moderate, and during the past few years the disease has increased with alarming rapidity I wonder if this increase is in any way due to the increased duty on whisky which practically prohibits its extensive use I would be interested to know if any other general practitioners have had a similar experience to mine, for if it could be proved that whisky was a preventive it might open up a field for experiment in treatment with whisky or one or more of its constituents

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 37, 41, 42 and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 38 39, and 40

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 132

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

263. "Spasmodic Diphtheria.

G W Ronaldson (*Brit Journ Child Dis*, July-September, 1924, p 182), who records two illustrative cases alludes to the cases of diphtheria associated with symptoms of irritation of the nervous system which have been described by French writers under the name of "diphterie spasmogene" The irritation may take the form of meningism or of pseudo tetanic seizures Previously recorded cases may be classified in three groups. The first consists of cases in which no diphtheritic membrane is found and the clinical picture is that of an acute affection of the nervous system Though no infective agent can be demonstrated in the cerebro-spinal fluid, diphtheria bacilli can be cultivated from the saliva, naso-pharynx, or conjunctiva In such cases the initial diagnosis is usually cerebro-spinal meningitis, rabies, or tetanus In several instances the symptoms rapidly subsided after injection of diphtheria antitoxin The second group, of which Ronaldson s first case is an example, consists of cases of clinical diphtheria accompanied by spasmodic nervous symptoms In the third group to which Ronaldson s second case belongs the signs of nervous irritation appear after disintegration of the false membrane Ronaldson considers that the number of well authenticated cases on record is sufficient to warrant the statement that symptoms of nervous irritation may be met with in cases where diphtheria seems to be the only possible explanation, but maintains that further proof is necessary before we can admit a diphtheritic origin for symptoms met with in subjects who show no clinical signs of diphtheria Commenting on this paper M Critchley (Ibid, p 188) under the title of post diphtheritic "chorea, records a case in a girl, aged 14, in whom symptoms of chorea developed after an attack of diphtheria in association with the ordinary phenomena of diphtheritic paralysis—namely nasal voice, paresis of accommodation and generalized polyneuritis Recovery took place within two months Critchley is of opinion that rheumatic chorea and polyneuritis could be excluded as well as epidemic encephalitis, and alludes to a similar case reported by Globus in a woman aged 29 who developed choreiform movements together with myoclonus as a complication of vaginal diphtheria Klebs Loeffler bacilli were obtained in cultures of the cerebro-spinal fluid There was no evidence of paralysis Mental changes supervened and death took place The autopsy showed definite acute inflammatory changes localized to the basal ganglia

234 Arterial Hypertension in Acute Nephritis

C Lian and J Haguenau (*Arch Mal du Coeur, des Vaisseaux et du Sang*, August, 1924 p 506) state that although much has been written on the cardio vascular complications of chronic nephritis since Bright s early researches, comparatively little attention has been paid to those accompanying acute nephritis Lian and Haguenau found in 7 soldier patients that the maximum arterial pressure was definitely increased in 6 and the minimum pressure in 5 In one case the blood pressure was only moderately high—a patient aged 20 years had a maximum pressure of 148 5 mm Hg with a minimum pressure of 138 He was not seen until a month after the onset of the acute nephritis, and it is probable that at the onset the blood pressure was considerably higher and had fallen progres sively None of these patients showed any signs of pre existing chronic nephritis In another series of observations on 11 soldiers only 3 showed manifest hypertension after the disappearance of acute symptoms Lian and Haguenau place the e cases in three categories a certain number recover completely in some a 'simple albuminuria persists without evidence of renal changes or hyperpiesis in other patients chronic nephritis, with or without hyper tension, supervenes but all authorities agree that this is rare The authors conclude that (1) acute or chronic nephritis is, in certain cases the exciting cause of transitory or permanent arterial hypertension (2) there are both transitory and permanent cases of hyper ension not due to nephritis 3) there are cases in which arterial hypertension either transien or permanent coincides with the bacterial in fection or with the intoxication which produces an acute or chronic nephritis Hyperpiesis may result from a dis turbance of the endocrino sympathetic system from certain toxins or toxic products in the absence of a renal lesion from certain nervous disturbances either direct or reflex or, lastly from the interaction of two or more of these proces es

265 Recovery in Pneumococcal Meningitis.

W Lieber (*Klin Woch*, September 2nd, 1924, p 1622) refers to the gravity of the prognosis in pneumococcal meningiti but cites cases of recovery in which the diagnosis had been confirmed bacteriologically Eugen Fraenkel states that 2 per cent of patients recover while Lubarsch estimates the ratio at 1 per cent The results of specific serum therapy have been generally disappointing, Schlesinger reports, however, three recoveries following administration of pneumococcal serum Morgenroth s optochin successfully used in very dilute (1 in 500 000) solution in pneumococcal keratitis has been recommended by several authorities in pneumococcal meningitis Wolff and Lehmann claim to have cured an infant, aged 8 months, by repeated intrathecal and intraventricular injections of optochin Loewe, Meyer, and L Valentin have recorded recoveries after its use, and Landsberger and Leschke recommend relatively large intrathecal doses of optochin Pieder records the following case which suggests that these writers have underestimated the therapeutic value of the simultaneous lumbar punctures A woman, aged 24 who had suffered from chronic double otitis media with perforation of both membrana tympani but who was otherwise healthy sustained a contused wound on the left side of the forehead subsequently she complained of headache, tinnitus, and irritability Four days later the eyelids were swollen and there were subconjunctival ecchymoses, she was deeply flushed with labial herpes and there were physical signs of early consolidation in the left lung The Kernig sign was positive the Babinski negative There was definite hyperaesthesia of the skin but no exacerbation of the chronic otitis media. The blood culture was sterile a blood count showed 10 000 leucocytes per cubic millimetre, the differential count was normal The Wassermann reaction of both the blood and the cerebro-spinal fluid was strongly positive Pneumococci were recovered from the spinal fluid Three further lumbar punctures were performed on alternate days 20-30 c cm of fluid was removed on each occasion and 20 c cm of physiological NaCl solution was twice injected into the spinal canal The temperature fell to normal on the twelfth day after the fall the headache and all other symptoms of meningitis disappeared, and the patient made a complete recovery Pieder observes that if optochin had been used in this case the *post hoc ergo propter hoc* argument might have been used The case shows that untreated pneumococcal meningitis is not necessarily fatal.

266 Small Doses of Iodine in Graves s Disease.

J Wahlberg (*Finska Läkaresällskapets Handlingar*, May-June 1924, p 385) confirms the observations of Neiser, published in 1920 which suggested that iodine may be beneficial as well as injurious in Graves s disease The author finds the problem is largely one of dosage and he gives even smaller doses than those recommended by Neiser Wahlberg gives iodine in the form of potassium iodide a 1 in 20 aqueous solution containing 0 0033 gram of potassium iodide per drop he does not give more than 15 drops in the day This treatment was given in eight cases of hyperthyroidism and in one case of vasomotor neurosis with a goitre The basal metabolism was investigated with Krogh s apparatus and there was in every case at first a reduction In most cases the pulse became slower and the patients felt better But the ultimate results were not so satisfactory as those of Neiser indeed there was only one case in which marked improvement was maintained. In two cases the disease became worse and this was probably on account of the treatment, a cumulative action of the drug having established its early beneficial effects But these early effects were so promising that the author considers this line of treatment deserving of further research

267 Measles without Eruption.

E Krasemann (*Monatsschr f Kinderheilk* 1924 xxvii p 513) remarks that cases of measles with an ill marked or entirely absent eruption have been seen more frequently since the introduction of the prophylactic use of convalescent serum In the first half of 1923 there was a severe outbreak of measles at Rostock and Krasemann noted that the eruption was absent in about 3 per cent of all the cases the diagnosis of these being based on exposure to infection the appearance of Koplik spots and the subsequent spread of infection Two such examples of this kind occurred in three brothers aged 2, 6 and 7 years respectively The symptoms in each case were nasal discharge conjunctivitis, cough irregular temperature slight bronchitis, and in two cases typical Koplik spots

parts of both thighs, apparently following the course of the circumflex iliac vessels The extravasation was blue red in colour, was neither tender nor sensitive to pressure, and when the true period began gradually disappeared The diagnosis from a traumatic extravasation in this case was easy, as there was no history of trauma, no tenderness, and the lesion appeared with absolute regularity eight to ten days before the beginning of each period Hirschberg considers the case one of complementary rather than vicarious menstruation, and ascribes the condition to increased permeability of the vessel walls, due to some disturbance in the endocrine equilibrium, though he is unable to explain why one vessel should be alone affected.

279 **Diagnosis of Sterility**

M HUHNER (*Amer Journ Obstet and Gynecol*, July, 1924, p 63) describes the tests which he employs in cases of sterility Microscopic examination of an unstained condom specimen of normal semen shows very many spermatozoa moving with extreme rapidity, if on early inspection the spermatozoa are few, dead, absent, or moving very feebly, and numerous Bottcher's crystals are present, the semen is certainly abnormal In cases of azoospermia thus detected surgical treatment of obstruction in the epididymis is only justifiable, according to Huhner, after the fluid from the testicle has been examined also, if numerous active spermatozoa are present in this the diagnosis of obstruction is correct and operation is indicated Absence of spermatozoa in the aspirated fluid may be due to an attack of mumps or to severe gonorrhoeal orchitis, in such cases operation would be useless A further test described by the author is that of microscopical examination of the fluid removed by pipette from the cervix uteri as soon as possible after coitus, the presence of numerous live spermatozoa shows that the male semen is not at fault, that the position of the cervix is physiologically suited for impregnation, and that the cause of sterility may reside higher in the female genital tract than the cervix A positive result of this test serves to exclude from responsibility for sterility (1) anatomical causes in the male, (2) premature ejaculation, (3) a possibly inimical action of the vaginal or cervical secretion on spermatozoa If the condom specimen contains live spermatozoa and the cervical specimen dead ones the female genital secretions may be unduly acid, and if then coitus be preceded by an alkaline douche, the cervical specimen may be found to contain live, active spermatozoa, thus furnishing a clue to treatment The finding of living spermatozoa in the fundus uteri two or three days after coitus, when spermatozoa in the cervix are dead or absent, signifies that sterility is due to (1) a small infantile uterus, (2) tubal obstruction, (3) ovarian abnormalities, or (4) disharmony between the germinal cells of the husband and wife The performance of the last mentioned test will indicate when operations for dilatation, curetting, or correction of uterine malposition are bound to be fruitless

280 **Menorrhagia and Radium Therapy**

R CROUSSE (*Gynécol et Obstet*, 1924, ix, 6, p 539) regards radium therapy as the last treatment to be tried, before resorting to hysterectomy, in severe and intractable cases of uterine bleeding in young women It has the advantage that some chance of child bearing is preserved, and the suggestion of recent experimental work, such as that of Lacassagne, that radiation in small doses may lead to deleterious effects on the ova and therefore the offspring, lacks confirmation at present He reported to the Belgian Gynaecological and Obstetric Society three cases resistant to other modes of treatment, in which small doses of radium, filtered through platinum and lead, were given by the vagina In the first patient, a nulli para aged 22, the second, third, and fourth next expected periods were missing and the subsequent ones were normal The second patient, a nullipara aged 28, had normal menses two months after treatment, and ten months later became pregnant and went to term In the third patient, a single woman aged 27, surgical treatment was contraindicated by reason of a haemophilic tendency two radium applications were followed by amenorrhoea, but by rectal and other apparently vicarious haemorrhages

Pathology.

281 **Action of Insulin on Blood Coagulation.**

LA BARRE (*Journ de Méd de Bordeaux et du Sud Ouest*, July 10th, 1924, p 531) pleads for the compulsory use of a method of insulin preparation, such as that employed by Banting, which will produce it in a purified form It is recommended that the insulin be [illegible] aqueous solution by ammonia sulp [illegible],

allowed to stand for twenty four hours, then centrifuged, and the supernatant fluid drawn off The precipitate (which contains the insulin) should be dissolved in 70 per cent alcohol, concentrated to one tenth of its volume, and added to 94 per cent alcohol, by which the insulin is again precipitated After further centrifugalizing the alcohol is removed, leaving a fine white powder of pure insulin In a series of experiments the author has demonstrated that if "impure" insulin be employed there is delay in clotting both *in vitro* and *in vivo*, and when only extremely small amounts were used The main action appeared to be an inhibition of the interaction between the fluid and cellular elements of the blood which normally results in the production of thrombin With "pure" insulin, on the other hand, no such delay in clotting was observed The author is of opinion that the retarding action of impure insulin is to be attributed to the presence of derivatives of choline or analogous substances In the usual dose of insulin (which he gives as ten units) there is present about 80 mg of choline, and it has been found that 2 5 mg of the latter will arrest the process of clotting, while even 0 5 mg will retard it Moreover, it has been noted that impure insulin contains products possessing a hyperglycaemic action and opposing the hypoglycaemic effects of insulin prepared according to the method given above As it has been found that choline injected intravenously into the dog causes a short hyperglycaemia, and as pancreatic substance contains 0 015 per cent and blood serum only 0 0002 to 0 002 per cent of choline, the author considers that it is to the latter substance that the hyperglycaemic action of impure insulin is to be attributed—an additional argument in favour of the employment of the purified product In conclusion he emphasizes the importance of using purified insulin in the injections now so frequently given prior to operation on diabetics, in support of which he cites a case recorded by Vermeuwe where the employment of an impure product resulted in profuse haemorrhage on account of the antithrombitic action produced

282 **Stability of Pneumococcus Types in Sterile Abscesses**

PREVIOUS work has shown that *B typhosus* and *B pestis caviae* become relatively inagglutinable when grown in sterile fixation abscesses in mice E MEGRAIL and E E ECKER (*Journ Inf Dis*, July, 1924, p 1) have now made experiments to test whether the same results occur in the case of the pneumococcus A 2 per cent suspension of gum tragacanth was injected subcutaneously into mice and rats After a time varying from six to twenty-four hours a salt suspension of a blood agar culture of a type pneumococcus was injected into the resulting abscess, the organisms were withdrawn when the animal showed signs of serious illness, and were then passed through another animal, and so on till several passages had been accomplished The biological and agglutination properties of the organism were studied before and after the transfers to ascertain whether any changes had occurred Several experiments, varying in details, were carried out, but in no case was any change found to take place Inulin fermentation and bile solubility remained unaltered in the passed strains, in only one case was the agglutination titre lowered through passage, in all the remaining cases it was the same as before Even when the animals were kept alive longer by the injection intraperitoneally of immune serum, and the organisms remained in contact with the abscess contents for a greater time than they otherwise would have done, the agglutination reactions were unchanged From these experiments the authors conclude that the pneumococcus has a type stability when placed under conditions in which typhoid bacilli and other organisms show variability It may be noted that they were working with whole cultures, not with single colony strains

283 **Fungi in Diarrhoeal Conditions**

M S FLEISHER and M WACHOWIAK (*Amer Journ Med Sci* September, 1924, p 371) studied culturally the relation of fungi to diarrhoeal conditions in a series of 32 cases, in 2 of which the fungi were isolated from the stools and, in some from the blood In rabbits the organisms caused diarrhoea and even death, and were found in the blood and internal organs of some of the animals Although monilia, or similar organisms, may be present in normal stools they are relatively infrequent, and yet in this series of 32 cases, in which diarrhoea was a prominent symptom, such organisms were present in the stools in 62 5 per cent In some of these cases identical organisms were demonstrated in the blood thus pointing to a causal relation between the organisms and the symptoms This view is further supported by the presence in the blood stream, as also by the improvement following vaccine therapy in some of the cases The author add that organisms of this type should be suspected in chronic diarrhoeas otherwise unexplained

De Dion Bouton

THE DOCTOR'S CAR

Note Width of Front Seat Comfortable Room for Three Adults

1925 MODEL, 12/28 H.P. COUPÉ = £665.

BE WISE IN TIME and make a careful note that this year's **Motor Show** at **OLYMPIA** starts **October 17th,** and lovers of **Automobilism** cannot afford to miss this opportunity of viewing at close quarters the **World's Best Cars.** Foremost in this collection of motive thoroughbreds, the discerning visitor will easily discover the celebrated **De Dion Bouton Cars,** for years acknowledged by cognoscenti to be without rival—in motor efficiency and road worthiness

The long wheel-base of the De Dion Chassis enables a particularly roomy body to be built—giving the maximum travelling comfort to driver and passengers The superb bodies, built with meticulous care by British Craftsmen, together with the beauty of the whole ensemble, make the De Dion Bouton a most desirable car to possess

All enquiries at DE DION BOUTON Stand No. 212 will be fully appreciated and carefully gone into without entailing any obligation

Exide

The long life battery

Delay is Dangerous

Battery life and human life have much in common

Properly fed and cared for the battery on your car will do its work cheerfully for a prolonged period. If it is neglected and ill nourished it becomes anaemic and will develop coma.

Battery troubles on Doctor's cars frequently suffer from insufficient charging to keep the cells in good condition.

Your nearest Exide Service Agent will arrange for the loan of a battery whilst your own is receiving attention in a periodical bench charge.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS

Special Preparations for all Surgical Qualifications.

F R C S ENGLAND (Primary & Final)	CH M, EDINBURGH
	M C CANTAB
F R C S EDINBURGH	M S LONDON

And all other Surgical Degrees and Diplomas

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy

¶ Both at the Primary and Final F R C S England the majority of our Students are successful at the first attempt and Candidates who have failed at these Exams on several previous occasions get through without difficulty after going through our courses

¶ The Surgical Tutors of the College all hold either the M S Lond or F R C S England or both, and are highly experienced teachers

¶ The Postal Courses are thoroughly clear concise, and up-to-date and the test questions are carefully selected from those set at previous Examinations so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time and much unnecessary reading is saved

Full Lists and Samples on application

This preparation is now obtainable in 5-oz. bottles

MIST. HEPATICA CONC. (Hewlett's).

COMPOSITION—Ext. Cascaræ, Ext. Rhei, Jalapin, Podophyllin, Cocainæ Hydrochlor., 1 20th gr. in each fluid drachm.

This preparation does NOT come under the Dangerous Drugs Act

THIS excellent compound has now become a popular remedy in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice and in the Jaundice of simple Hepatic Torpor. In passive or habitual Congestion of the Liver so frequently met with it has been used with marked benefit.

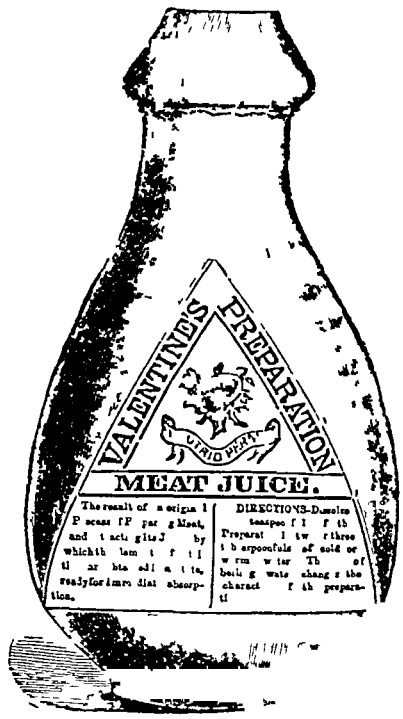
In the treatment of acute or temporary constipation frequently met with in the convalescence from acute disease and in pregnancy or in the constipation due to sedentary habits, the mixture can be prescribed with wonderful effect.

The Dose is from 10 to 60 minims according to the age and condition of the patient. One drachm is a direct aperient and is not accompanied by griping or tenesmus.

Packed for Dispensing only in 5-oz., 10-oz., 22-oz., 40-oz. and 90 oz. Bottles. Price in England, 12/8 per pound.

This preparation is also supplied sine Cocaina, the dose and price remaining the same.

C. J. HEWLETT & SON, Ltd., 35 to 42, CHARLOTTE STREET, LONDON, E.C.2.



Sole Agents for the HUMAN TUBERCLE BACILLUS SOLUTION (H.T.S.—CROFTON).

The most powerful tubercle bacillus antigen yet produced

Valentine's Meat-Juice

In **Typhoid Fever, Diarrhoea and Cholera Infantum,** when it is **Essential** to **Sustain** the patient **without irritating** the **Digestive Organs,** the **Ease** of **Assimilation** and **Power** of **Valentine's Meat-Juice** to **Restore** and **Strengthen** has been demonstrated in Hospital and Private Practice.

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

WITH SUPPLEMENT.

No 3329 SATURDAY, OCTOBER 18, 1924. Price 1/3

℞ Syr. Cocillanæ Comp. P.D. & Co.

Each fluid drachm contains	
Tinct. Cocillanæ	5 minims
Tinct. Euphorbiæ Pilulifera	15 minims
Syr. Wild Lettuce	15 minims
Syr. Small Comp. U.S.P.	3 minims
Cascarin (P., D. & Co.)	1 grain
Diacetorphine Hydrochloride	1/2 grain
Menthol	1 1600 grain

(Exempt from D.D.A. restrictions)

Syrup Cocillana Compound has been found excellent for the relief of hard, dry cough, and for general bronchial irritation.

It is pleasant to the palate, attractive in appearance, and the inclusion of Cascarin assists natural peristaltic action.

ISSUED WEEKLY] [COPYRIGHT] [REGISTERED AS A NEWSPAPER

This is the *genuine* Antiphlogistine Over 100,000 physicians prescribe it continually

What it is. Antiphlogistine is the most scientific, sanitary poultice known. It is composed of chemically pure glycerine, compounds of iodin (representing a small percentage of elementary iodin) minute quantities of boric and salicylic acids and the oils of peppermint, gaultheria, and eucalyptus, in a silicate of aluminum base

Indications. Antiphlogistine is indicated in all conditions in which inflammation and congestion are present, from a furuncle to pneumonia It offers the best known method for the prolonged application of moist heat. By the physical property of Osmosis and its ability to stimulate the cutaneous reflexes, Antiphlogistine assists in maintaining the blood and lymph circulation in the affected part, and hastens the elimination of toxins.

Its Action is graphically explained in the charts at the bottom of this advertisement.

The genuine Antiphlogistine may be relied upon in the treatment of any condition in which inflammation and congestion play a part.

The *genuine* Antiphlogistine, as scientifically compounded for 30 years by the Denver Chemical Manufacturing Company is the world's most widely used ethical proprietary preparation.

Let us send you literature covering all conditions in which Antiphlogistine is indicated

The Denver Chemical Mfg. Company,
London, E. 3.

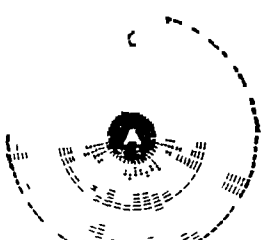
Antiphlogistine
TRADE MARK

"Promotes Osmosis"



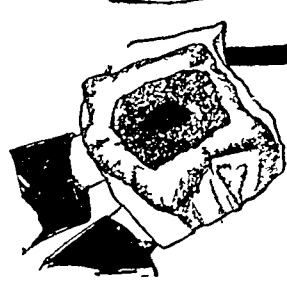


Diagram represents inflamed area. In zone "C" blood is flowing freely through underlying vessels This forms a current away from the Antiphlogistine, whose liquid contents, therefore, follow the line of least resistance and enter the circulation through the physical process of endosmosis In zone "A" there is stasis, no current tending to overcome Antiphlogistine's hygroscopic property The line of least resistance for the liquid exudate is therefore, in the direction of the Antiphlogistine. In obedience to the same law exosmosis is going on in this zone, and the excess of moisture is thus accounted for

Antiphlogistine poultice after application. Center moist. Periphery virtually dry

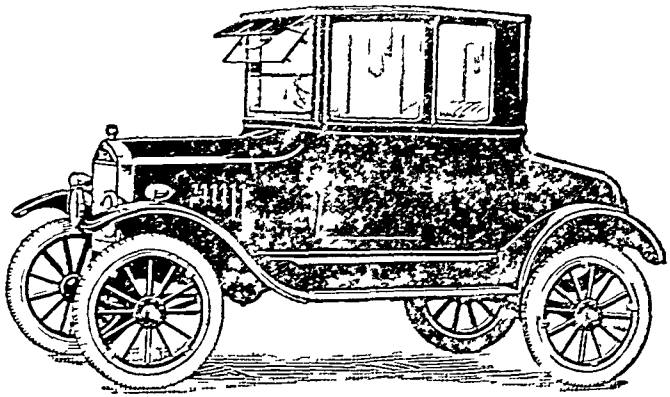
THE TALE OF THE EXHAUST

The exhaust gases of your car should be almost colourless It they are blue it indicates an excess of oil, if black and sooty the mixture is incorrect and the result will be a fouled engine To avoid trouble, adjust the carburetter carefully once and for all and then run on "BP," the British Petrol You will always be right after that because "BP" never varies It can be relied upon to provide maximum power in all conditions



"BP"

The British Petrol

The Practitioner's Car

THE reason for the popularity of the Ford Coupé among professional men of all countries is that it so effectively meets the vital needs of efficiency, reliability, weather protection, and economy

In the new 1924 Model the body design, form of chassis, easy driving, and silent running, impart a dignity to the Ford Coupé that meets at once the doctor's particular wishes and requirements

Comfort, appearance, simple control, low petrol consumption, easy starting, quick acceleration, are all points the doctor looks for The Ford Coupé possesses them to a greater degree than probably you have thought possible

LEADERSHIP

THE prestige that has been won by leadership is maintained and, shall we say, enhanced by the introduction of a new Calcott—the 12-24 h p It is a car eminently designed for those who respond to excellence All who have seen this car admit that it has a marked smoothness in action, a flow of power and riding comfort that only comes from a well-bred car displaying in its conduct the heritage of a long line of ancestors A remarkably fine car, moderately priced No mass production effort, but a car designed right and built with the care of a craftsman A car with qualities that preserve leadership—a car just a little ahead of its time Three-Seater, £365 Four Seater, £375 4/5-Seater Saloon, £525

The new 10-15 Calcott for 1925 has been re-designed, enlarged, and improved to such an extent as to immediately place it above the average "light car" class In power, roominess, comfort, and completeness of equipment it is equal to many cars of higher rating and cost De Luxe Two Seater Semi-Coupé £275 De Luxe Four Seater £275 Popular Two Seater, £255

Kraft Cheese

Kraft Cheese is selected for quality, blended for flavour, pasteurized for purity, and sealed in tinfoil for cleanliness.

Its high dietetic value is due not only to the compact nourishment that it offers, but to its high content of lime and phosphorus, its superior richness in butter fat, and its perfect purity

The pasteurization destroys gas-producing bacilli, but leaves all vitamins intact.

In many cases where ordinary cheese is found indigestible and irritating, Kraft Cheese can be taken with benefit. Authoritative opinion testifies to its worth, for general and particular use.

BRITISH MADE

Kraft Cheese

For everyone, every day

The Advantages of Cystopurin in the treatment of PROSTATIC ENLARGEMENT

"Prostatic enlargement," as Hutchinson has pointed out (Practitioner December 1921) "may by back pressure over a considerable period result in renal inefficiency with chronic uraemic symptoms and these may in turn give rise to gastro intestinal irritation. These are usually relieved by emptying the bladder, but this operation should be carried out very gradually Plenty of bland fluids should be taken, the bowels should be carefully attended to and the patient should be encouraged to get out of bed for short periods as often as possible. Coupled with this I have found that the use of Cystopurin has averted a number of complications, and I insist on its use before and after prostatectomy in every case." — *From a distinguished physician writing on the subject of The Treatment of Infective Conditions of the Urinary Tract"*

CYSTOPURIN

(The Ideal Urinary Antiseptic)

Clinical samples and literature will gladly be sent to any member of the medical profession upon request to the sole manufacturers

BILINA NATURAL SPRING WATER.

(Naturally slightly effervescent)

From the Famous Spring in Czechoslovakia

Unsurpassed in KIDNEY and BLADDER ailments GOUT RHEUMATISM and similar disorders
Unrivalled in DIGESTIVE and STOMACHIC troubles such as HYPERACIDITY HEARTBURN FLATULENCE CHRONIC CATARRH LOSS OF APPETITE etc
Unequalled for ailments of the RESPIRATORY ORGANS such as CATARRH OF THE THROAT LARYNX BRONCHIAL TUBES and LUNGS etc
Its saline constituents and the degree of concentration specially fit it for use in CHRONIC KIDNEY and GASTRIC DISORDERS
The small amount of sodium sulphate it contains confers on it slightly laxative properties and it can be recommended for regular use to those of constipated habit
Bilina Spring Water is entirely natural and the Carbonic Acid gas it contains gives it a most refreshing flavour It is unrivalled as a Dietetic Table Water Mixed with MILK LEMON or other fruit juices WHISKY and BRANDY it forms an extraordinary agreeable drink

PARATHYROID & CALCIUM THERAPY

Elixir Parathyroid (SQUIRE) and Elixir Parathyroid with Calcium (SQUIRE)

The internal secretions of the Parathyroid Gland have been found to play an important part in the proper assimilation and retention of Calcium in the tissues and, in consequence to exert a considerable influence on the nervous system and healing processes
There is abundant evidence that Parathyroid insufficiency may be compensated by the oral administration of the Parathyroid substance
The above Elixirs present in an agreeable and useful form the hormones of the Parathyroid Gland alone and in combination with a freshly prepared Calcium Lactate These preparations are specially indicated in TETANY, SPRUE PARALYSIS AGITANS certain forms of EPILEPSY, and in conditions of chronic SEPSIS such as varicose and duodenal ulcers In the treatment of CHILBLAINS excellent results have been obtained

Elixir of Parathyroid contains 1/10th of a grain of dried Parathyroid Substance in each fluid drachm Dose —20 to 60 minims
Elixir of Parathyroid with Calcium contains 1/40th of a grain of dried Parathyroid Substance and 2 grains of Calcium Lactate in each fluid drachm Dose —1 to 1 teaspoonfuls daily

The Elixirs are put up in Bottles containing 4 ozs , 8 ozs , and 16 ozs each

NATURAL CARLSBAD SPRUDEL-SALT

Prepared only by the Municipality of Carlsbad from the World famous "Sprudel" Spring at Carlsbad
(IN CRYSTALS OR POWDER)

Is the Only Genuine CARLSBAD SALT

Largely prescribed in cases of Chronic Gastric Catarrh, Hyperæmia of the Liver, Gall Stones, Chronic Constipation, Diabetes, Renal Calculi, Gout and Diseases of the Spleen, arising from residence in the Tropics or Malarious districts

As the NATURAL SPRUDEL SALT in crystals deliquesces at a temperature of 88° Fahrenheit the Sprudel Salt in powder form will be found more convenient seeing that it is not affected by high temperatures or exposure to the atmosphere

Medical Practitioners should kindly note, when prescribing, to specify "Carlsbad SPRUDEL Salt on account of the many artificial preparations upon the market

The wrapper round each bottle of genuine Salt bears the signature of the Sole Agents—

The normal functioning of Lymphoid Tissue

Marmite an Invaluable Agent

IT has now been established that the absence of B Vitamin from the diet causes atrophy of the lymphoid tissue, including the spleen, thymus gland and Peyer's patches, and a diminution of the small lymphocytes in the blood (*Lancet*, Dec 10th, 1921, pp 1202-1209 and 1228, and *Lancet*, March 29th, 1924, p 633)

If the dietary error is not corrected, loss of appetite, intestinal stasis, malnutrition, marasmus and ultimately death result The restoration of B Vitamin to the diet in the form of Marmite, a food especially rich in B Vitamin, readily removes the untoward symptoms and danger

Marmite is a preparation of Yeast It is so extremely palatable that it forms an appetising addition to soups, stews and all meat dishes It also makes an excellent sandwich Medical men will therefore find Marmite a readily acceptable food for patients suffering from conditions which indicate a need for increased supplies of B Vitamin

Marmite

Medical Practitioners are invited to write for a sample of Marmite, together with full evidence of its usefulness

ADVANCE IN TREATMENT of *Hyperchlorhydria and Associated Conditions*

TRADE MARK **ALOCOL** BRAND

Colloidal Hydroxide of Aluminium

Modern medical experience has proven that while the usual alkalis and oxides possess power for neutralizing the normal or abnormal acids of the stomach their action is only symptomatic and transitory They may give momentary relief to the painful condition, but they also have the effect of aggravating the morbid condition For this reason they are distinctly contra indicated, especially in stubborn cases

Alocol does not neutralize acid it absorbs the excess colloido chemically and at the same time leaves a sufficiency for normal gastric digestion The outstanding advantage of "Alocol as an intacid is that it removes from the stomach the excess of the acid radicle (Cl) instead of merely temporarily neutralizing it Alocol can be used for prolonged periods without the slightest harmful effect

A supply for clinical trial with full descriptive literature sent free on request

M. 197

'Alocol is indicated in all conditions in which diagnosis reveals high gastric acidity It is particularly valuable in the treatment of chronic affections of the stomach the dyspepsias, especially those of pregnancy gastric and duodenal ulcer gastrosuccorrhea and in conditions characterized by gastralgia, pyrosis flatulence, acid eructation and other symptoms common to gastric disease

PETROLEUM

IN THE TREATMENT OF

INTESTINAL DISORDERS

Purified Petroleum in one form or another is becoming more and more widely employed in the treatment of intestinal disorders associated with toxaemia To obtain the best results the petroleum should be not only non-irritating and free from all impurities, but it should preferably be in the form of an emulsion In this form, the minutely divided petroleum globules mingle freely with the intestinal contents, and are more widely and evenly distributed throughout the entire intestinal tract Maximum lubrication is thus assured and the characteristic action of the oil obtained with greater uniformity

Angier s Emulsion is made with a specially purified petroleum of just the right degree of viscosity It is a perfect Emulsion of cream like appearance and consistency, and mixes instantly with water and other liquids Pleasant to the palate and remarkably well borne by sensitive stomachs, it can be administered either undiluted or in any suitable vehicle It has been found that patients who cannot tolerate clear petroleum are able to take Angier s Emulsion without the slightest difficulty, and continue indefinitely without ever developing an antipathy to it Angier's Emulsion will also be found most useful as a vehicle for the administration of intestinal antiseptics or astringents, for which purpose it is eminently suitable

'After long experience of many forms of paraffin and petroleum both in the character of emulsions and otherwise I have found none so satisfactory to the patient as Angier's Petroleum Emulsion"—M D, D Sc, M A

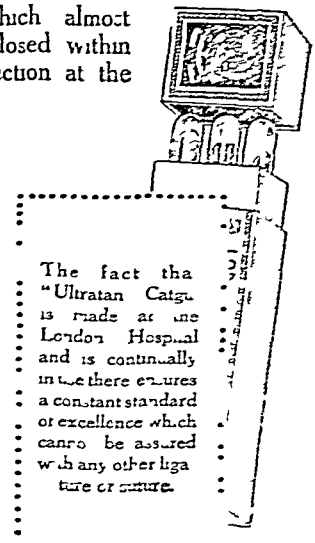
LONDON HOSPITAL CATGUT

STERILITY → The sterility of every batch is verified by bacteriological control both aerobic and anaerobic tests being carried out.

ABSORPTION → The time factor of absorption is practically constant and can be guaranteed in every grade

TENSILE STRENGTH → The tensile strength is such that even in the finest gut there is a wide margin of safety Every batch of London Hospital Catgut is tested by a specially designed machine which accurately registers the breaking strain



"Ultratan" Catgut is prepared under the strictest aseptic conditions in the special laboratories which have been set up for the purpose at the London Hospital, and is in use in the 15 operating theatres there The unique feature is that sterilisation commences immediately after the splitting of the intestine before the gut is twisted This ensures that no contaminating debris (which almost invariably would escape sterilisation) is enclosed within the turns, later to become the focus of infection at the site of operation

The London Hospital Eyeless Needles avoid the possibility of catching or laceration owing to absence of drag These aseptic needles straight curved round or cutting are supplied complete with sterile sutures packed in glass tubes ready for immediate surgical use.

Descriptive Book let will be sent post free upon application to the Sole Distributors

Allen & Hanburys Ltd.
48 WIGMORE ST.,
LONDON, W 1

The fact that "Ultratan Catgut is made at the London Hospital and is continually in use there ensures a constant standard of excellence which cannot be assured with any other ligature or suture.

DISCUSSION ON CARDIAC IRREGULARITIES, ESPECIALLY IN REFERENCE TO PROGNOSIS AND TREATMENT

OPENING PAPERS

I—T WARDROP GRIFFITH, C M G, M D, F R C P,
Professor of Medicine University of Leeds Physician Leeds General Infirmary

I HAVE been asked to open a discussion on irregularities of cardiac action with special reference to prognosis and treatment At the outset I may say that, while I have no quarrel with the title of the discussion, we shall find that in many cases we are more concerned with the underlying or associated conditions than with the actual irregularity I must try to respect the limitations imposed upon me by the title, and certainly the width of the subject ought to satisfy the aspirations of anyone It will however be necessary for me to state briefly the outstanding facts as to our present knowledge of the irregularities of cardiac action

There is nothing more instructive than to turn to the writings of the older observers and read them in the light of our present knowledge If we do this we shall rise from the task with a feeling of deep admiration for the accuracy of their observation To them we owe the classification of cardiac irregularities into those of time and force and the statement that these are often combined To that special form of irregularity of the pulse in which one beat in an otherwise regular series is missed out the term "intermission" was applied It was clearly grasped that in some cases this was the expression of a true intermission of cardiac action and that in others a weak beat had failed to reach the wrist. In this connexion Balfour quotes with critical approval the remarks of Hope, who had commented on the mistakes made by the "non auscultators" We shall however come to the conclusion that even Balfour was too ready to accept as a true intermission that which we now regard as due to a premature systole

I like to think that the old writers in contrasting irregularity with intermission were expressing the difference between that complete arrhythmia which we now know to be the hall mark of auricular fibrillation and that dropping of a pulse wave which is usually the expression of an extra-systole When they said that irregularity was a more serious matter than intermittence we shall agree with them —with this reservation that the intermittence we have in our mind is that due to a premature systole and not that due to a partial heart-block

It would not be possible to exaggerate the importance of the work of Sir James Mackenzie on the venous pulse which has done so much to elucidate many of the varieties of irregularity, nor is it possible for anyone who has tried as I have admiringly, to follow the work of other to study the writings of Sir Thomas Lewis on the electrocardiograph without feeling that in his experimental work and in his clinical observation alike he has immensely raised the prestige of British scientific medicine

I shall assume that we are in agreement in believing that the sino-auricular node is the normal site for the starting of each cycle of cardiac contraction because it is here that the stimulus material reaches the flash point soonest, and that the excitation and the contraction waves pass very rapidly over the auricles slowly through the node of Tawara and then so rapidly by the Purkinje network that they reach all parts of the ventricular musculature at periods which differ only by minute fractions of a second.

The accompanying table, for which I claim neither completeness nor originality, shows the chief forms of irregularity I make no more than a passing reference to those which depend upon variations in the attainment of the flash point by the sino-auricular node The influence of respiration, of exercise of emotion, and of various medicaments are all well recognized and need not detain us nor need the partially understood condition of sino-auricular block do so

Cardiac Irregularities

I Sinus arrhythmias
II From extra-systoles
  A Single (1) auricular (2) ventricular (3) auriculo-ventricular or nodal
  B Double or multiple of the same three varieties
  C Paroxysmal tachycardia
III From alternans
IV A V heart block
  A When complete (1) from ventricular extra-systoles (2) from the presence of two rhythmic centres
  B When partial (1) sporadic intermissions (2) rhythmical
V From sino-auricular block
VI From fibrillation and flutter

The irregularity which arises from auricular fibrillation must needs engage much of our attention, something must be said about extra-systoles and paroxysmal tachycardia and if time and space permit I should like to elicit some discussion on the subject of those irregularities which depend upon partial heart-block

AURICULAR FIBRILLATION

We are all familiar with the very common and serious form of irregularity which is associated with this condition for it prevails in more than 50 per cent of the patients admitted into a general hospital with symptoms of cardiac failure The history of the growth of our knowledge of this condition is both fascinating and familiar For many years a form of cardiac irregularity has been recognized in which there is complete arrhythmia in which large and small beats of the pulse follow one another in complete confusion with less than the usual relationship between the size of the beat and the length of the preceding pause To James Mackenzie belongs the great credit of pointing out the connexion of this with that form of venous pulse to which he gave the name of "ventricular," the normal evidence of auricular activity being absent His first and natural inference that the auricle was paralysed was soon given up when he found that the *post-mortem* appearances were far from that of a paralysed organ He then formed the opinion that auricle and ventricle were contracting at the same time owing to impulses coming from the auriculo-ventricular node to this condition he gave the name of "nodal rhythm," but with scientific caution he reserved his final opinion A very important stage was reached in 1909 when Rothberger and Winterberg on the one hand and Lewis on the other recognized the similarity between clinical curves from cases with complete arrhythmia and experimental curves obtained after fibrillation had been set up in dogs Lewis's papers showed the consistency of the polygraph venous curves with the assumption that the auricle was not taking part in their causation—other indeed than by showing slight waves during the longer pauses His electrocardiographic results were quite convincing and finally he was able to demonstrate the fibrillating auricle in a horse which had the affection and was killed by being shot through the head and had its heart immediately exposed to view

We now know that the presence of a pulse which has no recognizable rhythm, which is indeed non-rhythmical carries with it the sure inference that it owes its lack of rhythm to this condition The behaviour of the auricle is such that, while it loses all power of propulsion of the blood it showers irregularly toward the auriculo-ventricular bridge hundreds of stimuli of which probably many never cross the bridge, and of those that do some may be so weak as not to elicit any response Those that do and are strong enough to elicit a response reach the ventricle at irregular intervals, and, in harmony with the 'all or nothing'" behaviour of the heart pointed out by Bowditch, the contractions will be the result of

which the ventricle is capable at those particular moments when the stimuli reach it As the stimuli reach the ventricular musculature at irregular intervals, and as the strength of a ventricular contraction seems usually to depend upon the duration of its period of rest, we find that the beats do indeed vary in strength and efficiency But careful inspection of tracings shows that this simple relationship is not characteristic of the irregularity of fibrillation, for weak beats may follow long pauses and strong beats may follow short pauses That a weak beat should appear to follow a long pause may find an explanation in the long pause being so in appearance only it may have contained one or more weak beats which had used up the energy of the muscle A greater difficulty is presented by a short pause being followed by a strong beat Probably here the explanation is allied to that advanced by Gaskell in his discussion on the pulsus alternans The muscular fibres of the heart do not all recover at the same rate, the strength of any contraction will depend upon the number that have so far recovered as to contract at all, and the vigour of their response will depend upon the degree of their recovery Considerations of blood supply may influence this, nor can the muscular fibres always be at concert pitch—"*neque semper arcum tendit Apollo*"

The development of auricular fibrillation is at times—and according to some frequently—ushered in by transient paroxysmal attacks, in other cases the frequent occurrence of auricular extra-systoles has been noted It is, however, certain that fibrillation of an abiding character is often found where there has not been any definite history suggestive of the actual date of onset So latent or so slight may the symptoms be that many of its subjects do not even seek medical advice, the usual avocations of life in the way of work or of sport are carried on, and the condition may be detected only when for some reason a routine examination of the heart is made On the other hand, the majority soon complain of dyspnoea and have the usual symptoms of cardiac failure combined with the characteristic non-rhythmical pulse with numerous imperfect beats, many of which do not reach the wrist even if they succeed in opening the aortic valve

The Influence of Digitalis

It has of course been well known for many years that the form of cardiac failure which is associated with a pulse and cardiac action devoid of rhythm calls for the free use of digitalis This was fully grasped long before the nature of the arrhythmia was understood, and I have sometimes thought that this has been overlooked We now know that the influence of digitalis in depressing the conductivity of the junctional tissues is especially developed in cases of auricular fibrillation, and that it is this property which makes it such a useful drug in the treatment of the cardiac failure with which it is associated A large number of stimuli which would formerly have passed to the ventricles, goading them into contractions for which they were unprepared, are now arrested Those stimuli which do reach the ventricles are separated by longer intervals, the ventricles have longer to recover and respond by stronger and more effective contractions It is to be noted that the fibrillation of the auricles continues—indeed it is said that the use of digitalis tends to its perpetuation—and that the arrhythmia persists

> Who is there among us who has not repeatedly seen tients admitted into hospital with profound cardiac ilure—shown by orthopnoea, dropsy, albuminuria, enlargement of the liver, venous fullness in the neck, cyanosis, and a pulse devoid of all rhythm—improve with rest in bed, and who can doubt that the free administration of digitalis has been followed by a slowing of the pulse, a diminution in the number of ineffective beats with a strengthening of others, and a recovery of adequate *arterial blood pressure*?

Opinions differ as to whether these beneficial effects arise purely from the diminution of the number of impulses reaching the ventricles, or whether, in addition to this, there is some direct action on the muscle of the ventricles by the drug As a result of clinical experience I am strongly of opinion that some such action must exist In cases of cardiac failure where the rhythm was normal, and where digitalis had been withheld on the ground that it was not likely to benefit the patient, I have given full doses with great benefit, I have seen dropsies and albuminuria go and the patient greatly relieved, though there has been little or no diminution in the frequency of the cardiac beats

I have said that the drug must be given in adequate doses I have very little experience of the administration of massive doses after the manner of Eggleston I have used the tincture in doses of 10 minims every four hours or oftener Sometimes the drug may cause a degree of heart-block which becomes complete, and in some cases during the development of this there have been no untoward symptoms, but this consummation should be avoided as excessive and not devoid of danger When the action *of the heart becomes infrequent* under the influence of the drug, extra-systoles of ectopic origin begin to show themselves These arise in either the right or left ventricle, or sometimes in one and sometimes in the other Now an occasional extra-systole when the heart is slowing down under digitalis does not call for the stopping of the drug, but when they begin to appear rhythmically or even very often, though irregularly, after normal beats it is generally held that the drug should be lessened or stopped I do not go so far as Lewis in this matter, and I have continued the use of the drug even when extra-systoles were frequent and rhythmical Still I agree that caution is necessary

It is the case, therefore, that there are a great many people who, in virtue of Withering's great discovery of the merits of digitalis and of the extended knowledge which has led to a more efficient use of the drug, are leading useful and in some cases active lives while they still have auricles which are fibrillating

The Influence of Quinidine Sulphate

It may again be mentioned that digitalis does not cause the fibrillation to cease and that the pulse *remains non*-rhythmical In 1914 Wenckebach quoted the case of a South African Dutchman who was in the habit of taking quinine for the relief of malaria and who found that a cardiac irregularity of which he was the subject lessened while he was under the influence of the drug Wenckebach's experience was that quinine abolished the irregularity of paroxysmal fibrillation, but had no effect on the more permanent variety In 1918 Frey suggested quinidine as being less toxic and more soluble, and the use of this drug in a systematic manner has gone hand-in-hand with an understanding of the true nature of the affection Here again we find ourselves on fascinating ground All that I know about this matter I have learned from the work of Lewis He gives the fullest credit to Romanes, to Mayer, to Mines, and to Garry, and as the result of elaborate experiments on dogs he has established on a firm basis the view that both auricular flutter and fibrillation are due to a circus movement of the wave of excitation and contraction which under certain conditions of impaired conductivity passes round a tract of muscle in the auricle and reaches the starting point at a time when the muscle has recovered its power of response In this way a continuous wave of contraction passes round and round the course, there being always a short portion of responsive or partially responsive muscle between the advancing crest of the wave and its returning tail He has produced *both conditions in the dog* by electrical stimulation, and has found that the one may pass into the other He seems to have proved that in flutter the ambit of the circus—the length of the course, in other words—is longer than in fibrillation, the former probably surrounding the two venae in a *common loop*, the latter surrounding it may be one caval opening In harmony with this the number of circuits in flutter varies between about 230 and 350, and in fibrillation it is about 400 to 500 In flutter the length of time occupied by the circuit is remarkably constant and the electrical *oscillations* vary only by almost immeasurable fractions of a second, in fibrillation the general course of the circuit may remain constant so far as can be made out, but the circuits vary in details of their exact course and in the time taken for their completion In both cases centrifugal waves of excitation p

off from this "mother wave" Those found in flutter are singularly regular and uniform from circuit to circuit, in fibrillation they are as in the case of their "mother wave," irregular The difference between flutter and fibrillation is therefore largely if not entirely, a question of the degree to which conductivity is impaired by the distribution of the barriers to the passage of the stimuli, a degree which is greater in fibrillation than in flutter

The experiments of Lewis carry conviction to my mind, and I am prepared to subscribe to his opinion that the former view which attributed fibrillation to a series of rapid impulses arising at one or more irritable centres in the muscle of the auricle to which it responds in a confused manner is no longer admissible

Now quinidine has two actions it lengthens the refractory period and it slows conduction in the auricular musculature It may be that the second effect is solely due to the first but it is clear that the second if acting alone, would tend to perpetuate fibrillation or flutter whichever was present The former effect may result in the excitation wave slowly passing though it may be reaching the starting point before the muscle has recovered and is capable of response Should this occur let us say in fibrillation it may be that an excitation wave passing by a longer circuit may reach the starting point after the muscle has recovered, and so flutter or impure flutter may be established With a further lengthening of the refractory period even this wave of excitation slower still it may be in its passage than when it entered into its kingdom of dominance may reach the starting point before the muscle has passed out of the refractory state The circular wave is now brought to an end and the sino-auricular node immediately comes into its own again During all the time that fibrillation or flutter has been prevailing it is almost certain that the sino-auricular node has been building up its stimulus material in the confident hope as it were of being able to initiate a stimulus as in the days of old but every time the excitation wave of the circuit comes round its small magazine of stimulus material is blown up and it has to begin again But it is not weary in well-doing it bides its time, and it has its reward when its rivals of fibrillation and flutter are put out of action by the closing of the circuit

My experience of the use of quinidine is not great enough to entitle me to speak with authority or to discourse on statistics I have followed in the footsteps of others and I have done so with caution I have adopted the usual plan of giving on a selected day two doses of 0·2 gram at an interval of two or three hours In the absence of any unfavourable reaction, doses of 0·2 gram have then been given every two hours either until the normal rhythm was restored, or until in all 2 grams had been given or until the drug had to be stopped on account of symptoms of poisoning The effect of the drug is well seen in the tracings shown in Figs 1 and 2

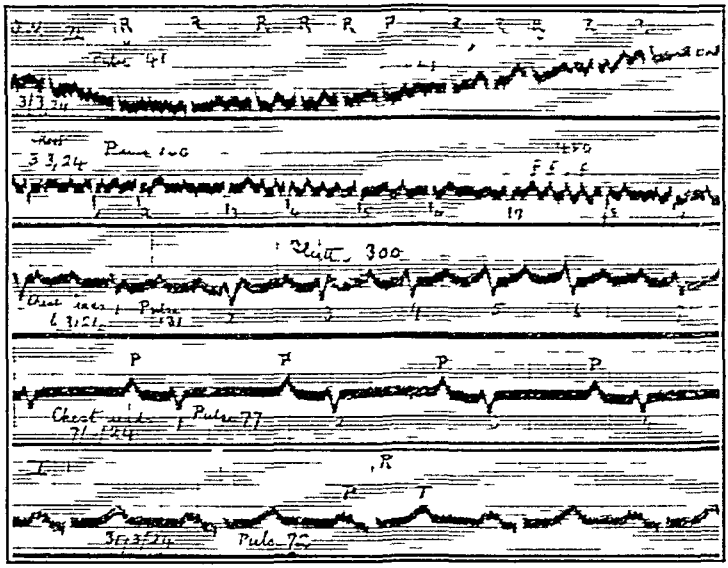

FIG 1—Case of mitral stenosis Patient aged 18 Fibrillation known to have existed for at least eight months First two tracings—Lead II and chest leads respectively—taken before quinidine was begun From March 6th at 4 p.m till March 8th at 4 a.m five doses of 0·2 gram given Tracing number 3 shows an almost pure form of fibrillation 300 per minute every second or third stimulus getting through to ventricle Some failure of drug being stopped Then from 10 a.m on the 6th till 4 a.m on the 7th nine last 0·2 gram were given Shortly after the last dose the patient suddenly was conscious that the throbbing in the neck had ceased and the pulse was found to be regular and infrequent Tracing number 4 taken by chest leads shows the restoration of the normal rhythm with a long P—P interval The I—tracing from Lead II shows some tendency to a shortening of this long P—P interval

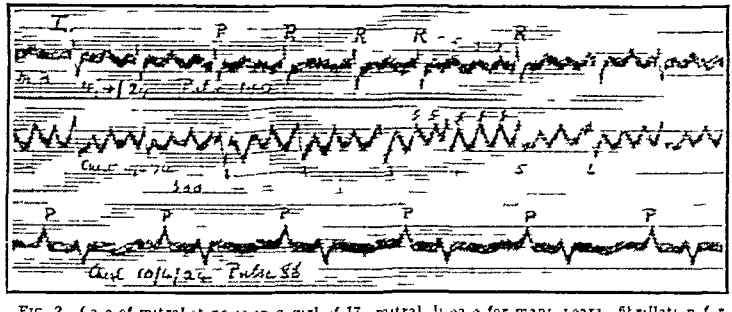

FIG 2—Case of mitral stenosis in a girl of 17 mitral disease for many years fibrillation for many months possibly more than twelve First and second tracings taken before treatment—Lead I and chest leads respectively On day of leaving test dose patient had 2 grams of quinine sulphate over a period of twelve hours in doses of 0·2 gram The third tracings—chest leads—shows the restoration of the normal rhythm

Now quinidine has two actions it lengthens the refractory period and it slows conduction in the auricular musculature It may be that the second effect is solely due to the first but it is clear that the second if acting alone, would tend to perpetuate fibrillation or flutter whichever was present The former effect may result in the excitation wave slowly passing though it may be reaching the starting point before the muscle has recovered and is capable of response Should this occur let us say in fibrillation it may be that an excitation wave passing by a longer circuit may reach the starting point after the muscle has recovered, and so flutter or impure flutter may be established With a further lengthening of the refractory period even this wave of excitation slower still it may be in its passage than when it entered into its kingdom of dominance may reach the starting point before the muscle has passed out of the refractory state The circular wave is now brought to an end and the sino-auricular node immediately comes into its own again During all the time that fibrillation or flutter has been prevailing it is almost certain that the sino-auricular node has been building up its stimulus material in the confident hope as it were of being able to initiate a stimulus as in the days of old but every time the excitation wave of the circuit comes round its small magazine of stimulus material is blown up and it has to begin again But it is not weary in well-doing it bides its time, and it has its reward when its rivals of fibrillation and flutter are put out of action by the closing of the circuit

My experience of the use of quinidine is not great enough to entitle me to speak with authority or to discourse on statistics I have followed in the footsteps of others and I have done so with caution I have adopted the usual plan of giving on a selected day two doses of 0·2 gram at an interval of two or three hours In the absence of any unfavourable reaction, doses of 0·2 gram have then been given every two hours either until the normal rhythm was restored, or until in all 2 grams had been given or until the drug had to be stopped on account of symptoms of poisoning The effect of the drug is well seen in the tracings shown in Figs 1 and 2

It is clear therefore that in a certain number of cases the normal rhythm of the heart is restored by the use of quinidine The answer to the question whether it should be used must depend upon the answers to the following What is the value of the restoration of the normal rhythm? and What are the dangers?

I Now the functions of the auricles of the heart are

(1) To act as reservoirs for the blood which reaches them during the ventricular systole when of course it cannot pass on

(2) To convey in harmony with their regular rhythmical action regular rhythmical stimuli to the functional tissues *en route* for the ventricles

(3) To propel that residual amount of blood which has not in obedience to other forces already passed into the ventricles during the earlier and greater part of their diastole

(4) By suddenly increasing the intravenricular pressure to lead to a closure of the auriculoventricular valves *before* the contraction of the ventricles takes place and so obviate that slight stretch of the muscle which is conducive to efficient response

Fibrillation does not interfere with the first of these functions it leads as we have seen to a great perversion of the second the third and fourth are not performed at all

The restoration of the normal functions of the auricle *ought*, one would think, to be attended with benefit There are, indeed, certain difficulties in understanding how the circulation of the blood goes on without the help of the

auricles These can be explained, it is true, but the propelling power of the auricle cannot fail to be an asset The influence of digitalis, though it lessens the number of stimuli reaching the ventricles, leaves them acting non-rhythmically—unless, indeed, complete heart-block has been caused The restoration of the normal rhythm will tend to equalize the amount of blood the ventricles have to deal with at each beat, and the regular call on their activities, one would think, must be favourable

In harmony with these views it is found that many of the patients express themselves as much better In the two cases of which I have shown the tracings one patient found on awakening during the night that the throbbing in her neck had gone, and both are now very much better than when the disorderly rhythm prevailed, though all medication has been suspended It has also been observed that when in some cases of cardiac failure the normal rhythm has been restored, good compensation has after a time been secured without any further use of drugs

II What are the dangers?

This is a very important matter, with which I must deal very briefly It is certainly the case that many unpleasant and some dangerous symptoms may arise after moderate doses of the drug, even when the precaution of test doses has been employed Among these may be mentioned nausea vomiting, palpitation giddiness, faintness, flushing, convulsions, syncope, apnoea, dyspnoea, and other signs of cardiac failure In some cases grave symptoms of respiratory failure have shown themselves, and in others the symptoms would appear to be explained by the sino-auricular node not taking on its function when the fibrillation ends In some cases where the patient was under the influence of digitalis at the time of the administration of the quinidine auriculo-ventricular heart-block has developed In some embolism has occurred

I must leave it to others with a greater experience than has fallen to my lot to advise us as to the dangers and how they may best be avoided The selection of suitable cases is important Those of short duration without great manifestations of cardiac failure do best, as might be expected

The question of dealing with cases in which there are marked signs of cardiac failure is very important It would seem best that these should be dealt with on the well understood methods of rest and digitalis, and that if thereafter it is deemed well to try to restore the normal rhythm a period of at least a week should be allowed to elapse before the quinidine is begun Here again I must leave the matter to the meeting

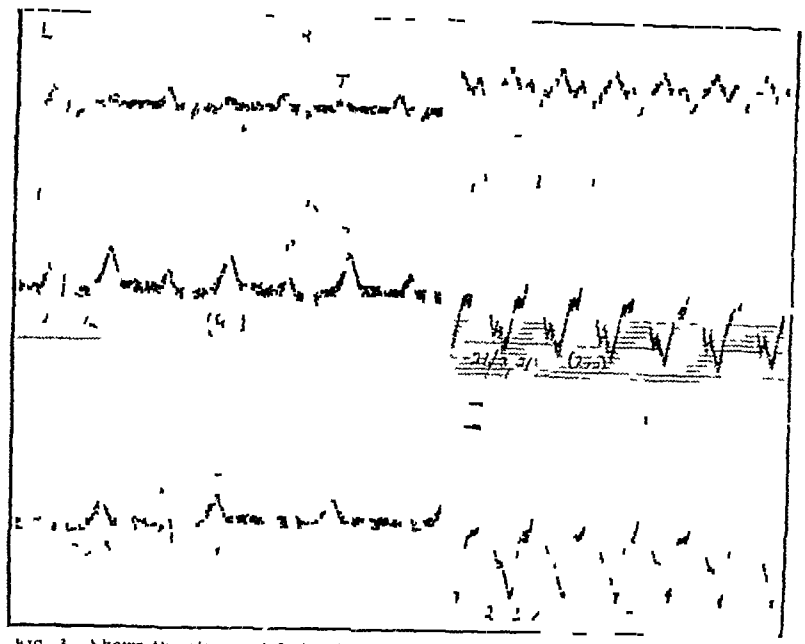

FIG 3.—Shows the slow and fast rates in a case of paroxysmal tachycardia Leads I, II, and III

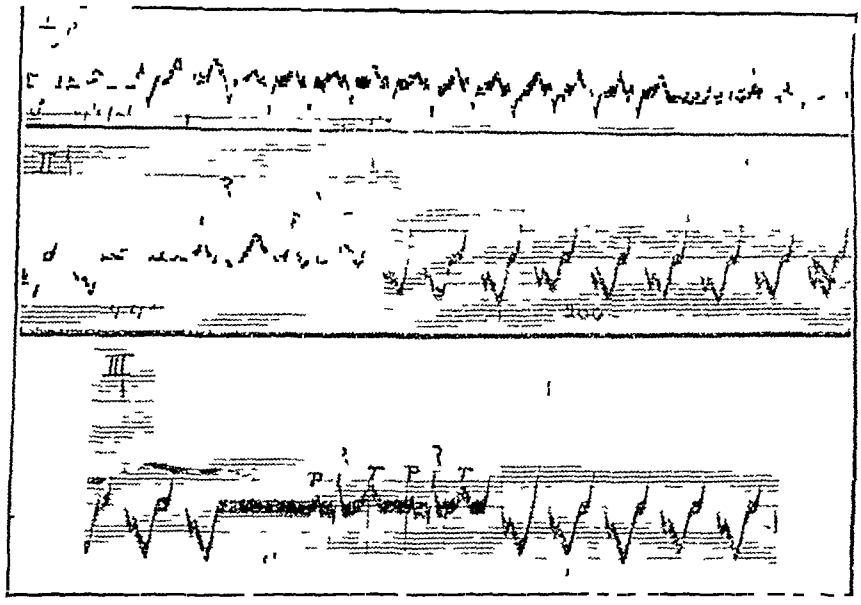

FIG 4.—Shows the beginning and ending of short paroxysms from a case Leads I, II, and III

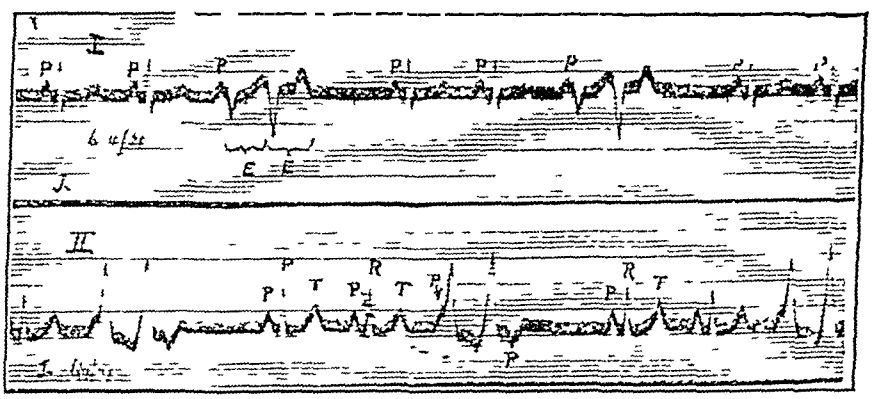

FIG 5.—Shows extra systoles occurring in couples from the same case as Figs 3 and 4 Leads I and II

Extra-systoles and Paroxysmal Tachycardia

It is well known that extra or premature systoles may arise in the neighbourhood of the sino-auricular node, in the general musculature of the auricle, in the node of Tawara, in the main bundle beyond the node, and in the right or left ventricle, where probably they arise in the Purkinje network All these varieties may now with certainty be distinguished from one another

In many cases the occurrence of extra-systoles is not noticed by those the subjects of them, but they may be associated with feelings described as if a "beat were missed out" or as if the heart were "tumbling over"

amount of discomfort, in some cases amounting to distress, varies greatly, some pay little attention to them, others of a more nervous disposition suffer greatly

These extra systoles can be produced experimentally in dogs by a great many different forms of stimuli applied to different parts of the heart and by such proceedings as clamping the aorta and by the injection of certain poisons The electrocardiographic records of these are all found to have their clinical equivalents

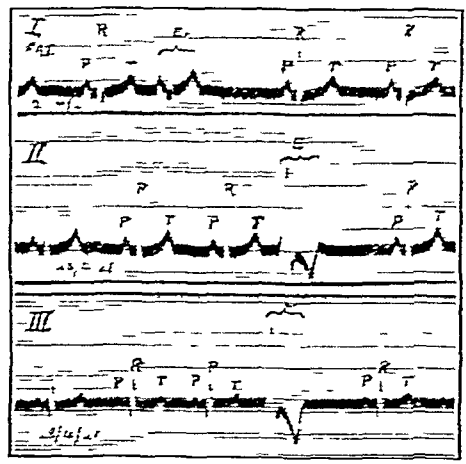

FIG 6—Shows isolated extra-systoles of right ventricular origin from the same case as Figs. 3 4 and 5a Leads I II and III

It seems a reasonable view to hold that isolated extra systoles are due to the presence at their points of origin of some irritable focus from which at time to time discharge takes place More especially in the case of the ventricles it happens that an extra systole may fall after every normal systole so that one cannot but think that the normal systole in some way causes the discharge which leads to the extra systole When a second extra systole follows after the first it may be that the first causes the second, if so it would appear that an extra-systole is not so potent to determine a discharge as is a normal one, because extra systoles are much more commonly isolated If in the same way the second extra systole gives rise to a third we are on the highway towards the condition known as paroxysmal tachycardia, between which and an isolated extra systole there would appear to be the same difference as there is between a regiment of soldiers and one man The tracings (Figs 3 to 6) show these transitions well The first extra systole of a paroxysm follows on a normal beat at a varying interval the second usually at a shorter interval than separates the beats of a fully developed paroxysm Each paroxysm is remarkably constant as to its rate The presence of some irritable focus sending out regular impulses would of course explain the phenomenon I am not aware of any experimental work which might support the view that here, as in flutter, some kind of circus movement underlies the condition It is very hard to understand the occurrence of extra-systoles occurring rhythmically and at longer intervals (Fig 7 lower tracing) Over long periods of time I have found both auricular and ventricular systoles following on every second, third, fourth or fifth beat sometimes after following every third beat changing to after every fifth or sixth and maintaining that rhythm for some time It has been tentatively suggested that the irritable focus may have a rhythm of its own and that some of its stimuli may reach the muscle during the refractory period of a previous contraction and produce no effect while others which cause extra-systoles reach the muscle at times when it can respond Alternatively it has been suggested that the irritable focus has a rhythm which varies This is a theory which I do not think can be seriously entertained In the case of rhythmical extra-systoles of auricular origin, separated by considerable intervals from one another, it is possible to think there may be some rhythmically acting influence coming to the heart from without but to account for similar extra-systoles of ventricular origin it is indeed difficult to picture to one's mind a portion say of ventricular muscle surrounded as it were like Brunnhild in the opera by one barrier which on the one hand protects it from having to participate in the successive contractions of the ventricle and on the other hand leaves it free to send out rhythmical impulses

FIG 7—Shows right ventricular extra-systoles occurring in upper tracing after each normal systole and in lower tracing after each second normal systole.

Clearly to recognize that a cardiac irregularity is due to the occurrence of extra systoles is of course a matter of prime importance It is sometimes very difficult and or rarely I think it is impossible to be certain without instrumental means The condition from which it has to be distinguished include the following

(1) Sinus arrhythmia which I shall not discuss here the distinction of importance in the case of those that follow

(2) Flutter and more especially fibrillation When we have extra-systoles thrown in irregularly and when one of these auricular interpolated beats may be well nigh impossible by the unaided senses to decide upon the cause of the irregularity and the distinction is very important

(3) True pulsus alternans This may bear a superficial resemblance to the condition in which a premature systole following after each normal beat causes the pulse bigeminus The distinction may occur easily made by instrumental means and the outlook is widely different in the two cases

It is not easy to say anything useful about the prognosis of extra systoles in some cases they appear to be of no importance but it must be admitted that they are more frequent in those who have cardiac valvular or muscular lesions and in those the subjects of increased blood pressure, that they often persist in spite of treatment that they may be associated with severe distress, that their very existence may develop a severe neurosis and that the patient cannot be reassured Again it is said that they may usher in the condition of paroxysmal tachycardia or of auricular fibrillation In most cases our prognosis will depend more upon the conditions associated with the extra systoles than with the actual irregularity itself, and our treatment will be dominated by the view we take as to these In cases where we find no organic disease of the heart we shall probably advise as to careful living with a strict avoidance of anything approaching to invalidism Open-air pursuit should be encouraged and a reasonable amount of exercise should be taken. The diet should be light mastication should be thorough, and the teeth should receive attention to make this possible to eliminate oral sepsis and to guard against flatulence Coffee should be avoided tea should be weak and fresh tobacco should be limited Many other precautions may doubtless be suggested Digitalis should be avoided though I fear it is often ordered, and the cautious use of ammonia bromide may give some relief It is of interest to note that some observers claim to have seen great benefit from the use of small doses of quinidine, both

in extra-systoles and in paroxysmal tachycardia Fred M Smith of Chicago is especially confident about this The condition of the patient in cases of paroxysmal tachycardia is often extremely alarming, and of course some patients die during an attack The sudden spontaneous cessation of the attacks makes it difficult to gauge the value of the different manœuvres, such as firm pressure on the abdomen, holding the breath after a full inspiration, etc, which are tried to cut them short I have on more than one occasion given morphine hypodermically during the height of an attack, with the happiest results In the treatment of the irregularity of the heart arising from extra-systoles steady *encouragement of the patient is most necessary*, for "A merry heart goes all the day, Your sad tires in a mile-a"

Pulsus Alternans

I have mentioned the condition of *pulsus alternans* In this every second beat is weak, and that without the excuse of being premature as in the case of the *pulsus bigeminus* The prognosis of this is so grave that it is necessary to mention that a short period of alternans may follow on a premature systole without exciting alarm, but if it shows any tendency to persist the outlook at once becomes serious The condition may be simulated in heart-block, complete or partial, when every second heart beat coincides with an auricular systole which prevents it having its full effect The occurrence of an interpolated extra-systole, so weak as not to be detected at the wrist, may also simulate the condition, and it may also be found after the administration of atropine When, however, these extenuating possibilities are eliminated we are certainly confronted with a very grave condition, and serious myocardial disease must be suspected I have, however, reassuring recollections of two cases of well marked alternans in which the patients did well one was in a frail woman with renal disease, who not only recovered but who subsequently survived an attack of pneumonia, the other was in a young man who had double pneumonia and pericarditis, and who afterwards joined the army and took his share in the great war

Heart-block

I must be very brief in what I say about the irregularities due to heart-block When the block is complete and of some duration the ventricle, which sets its own rhythm, usually acts regularly, but to this there are at least two exceptions One was pointed out by Wenckebach, and is due to the occurrence of extra-systoles originating in the ventricle and differing from those seen when there is no block in the post-extra-systolic pause being of the same length as those which follow on the rhythmical beats Another exception is provided by cases in which there appear to be two centres in the ventricular musculature with different rhythms, one or the other of which in turn determines the ventricular rate

When the heart-block is partial there may of course be no irregularity, as when every second auricular stimulus gets through But when a block occurs sporadically, or when every third or fourth auricular stimulus is blocked, irregularities of varying patterns are met with A mere lengthening of the period of auriculo-ventricular transmission, which is of course the mildest form of heart-block, causes no irregularity and its mention may appear irrelevant but it may be a condition leading to heart-block, and I have found it last after the other manifestations of heart-block have passed off The causes of heart-block are very diverse acute or chronic lesions, recoverable or not, may be present, and the prognosis, so far as the duration of the block is concerned, will vary in harmony with these

When a patient has partial heart-block it may pass off entirely and the P-R interval may in time become normal, on the other hand, it may become complete, and then the patient is usually better in health and more comfortable than when the block was partial, both when the block is partial and when it is complete he is liable to attacks of the Adams-Stokes syndrome, and any one of these may prove fatal When a patient has complete heart-block, even if of some considerable duration, it may pass off completely, sometimes passing through a phase of partial heart block and sometimes apparently without doing so

There are many points of interest in the management of cases with partial heart-block, but considerations of time and space alike prevent their discussion by me I am in hopes, however, that others may contribute to our knowledge of this important aspect of our subject

---

II—JOHN HAY, M.D., F.R.C.P.,

Senior Honorary Physician, Liverpool Royal Infirmary

May I first express my appreciation of the masterly and lucid presentation of the subject to which we have just listened? I do not think it could have been done better

In the time at my disposal I can do little more than underline some of the points referred to by the opener He described in detail the various forms of cardiac arrhythmia, and it is clear that prognosis and treatment alike depend on the recognition of the particular type of irregularity present Unless the nature of the irregularity is recognized prognosis is of necessity vague and hesitating, and treatment unsatisfactory I venture to say that there is nothing more important in the management of heart patients than the power to recognize the presence of auricular fibrillation

The war has done a great deal to focus attention on the heart, and there is now a far higher level of knowledge of this aspect of cardiac trouble, but even so there are many practitioners who have *no confidence* in their own *opinion* in the face of an abnormal cardiac rhythm It is essential that all should be familiar with the characteristic manifestations of this common and serious deviation from the normal—namely, *fibrillation of the auricle* In fibrillation the fundamental rhythm is lost, the action of the ventricle is disorderly and chaotic, and exercise aggravates the arrhythmia There is a tendency to consider a rapid ventricular action as an essential characteristic of fibrillation, but it is well to remember that even in the absence of treatment with digitalis the ventricular rate may be well within normal limits

It simplifies matters if we recognize that the more common irregularities can be arranged in two groups In the first group are the sinus arrhythmia, in which there is a rise and fall in frequency associated with respirations, and the arrhythmia due to the occurrence of premature beats In the second group are the disorderly action of auricular fibrillation and the alternating pulse Nearly every patient presenting an irregular action of the heart belongs to one or other of these groups

In the first group the prognosis may be considered good, other things being equal The presence of premature beats is, however, always an *indication* that a thorough examination of the patient should be made, especially in those of mature years The prognosis will depend on the associated conditions In the second group a guiding factor is the degree of distress induced by the onset of fibrillation from this it is possible to *gauge the integrity* or otherwise of the myocardium

The ventricular rate is also a guide—*the more rapid the* rate the more unsatisfactory the outlook, failure to respond to digitalis is an ominous sign, particularly if the fibrillation has been superimposed in a heart handicapped by a high blood pressure

The ominous import of an alternating pulse is now well recognized, I question, however, whether Professor Wilfred Griffith is quite justified in regarding the transitory alternation following an extra-systole with equanimity I believe it has the same evil significance as the fully developed pulsus alternans, although in a less degree Alternation occurring in a very rapidly acting heart is, of course, of little moment

The treatment of auricular *fibrillation* by quinidine sulphate has attained a degree of popularity at the present time and deserves our consideration Recently I have had the opportunity of pooling the results obtained by a number of observers, and the paper will shortly be published I may, however, say that in 166 cases of fibrillation associated with valvular disease quinidine was successful in restoring a normal rhythm for a period of more than three

months in 27 7 per cent in 87 cases of fibrillation in which there was no valvular disease the percentage of success was higher—namely 40 per cent The best results were obtained in patients affected by Graves's disease and toxic adenoma, in 12 patients a normal rhythm was restored and maintained in 66 per cent

In some of these patients partial thyroidectomy was an element in the treatment It has been found that the consequent diminution of the thyrotoxic condition facilitates the action of the quinidine A valuable paper by Dunhill, Fraser, and Stott in the July number of the *Quarterly Journal of Medicine*, deals with this aspect of the subject It is becoming more generally recognized that any septic focus interferes with the action of quinidine and should be radically dealt with before starting treatment It is probable that in the treatment of fibrillation by whatever mode of therapy every possible source of sepsis should be explored and dealt with

The last word in this discussion must be that the essential thing is the recognition of the nature of the irregularity present It is here that the difficulty lies and it is a matter of moment that every practitioner should make himself familiar with the clear clinical manifestations of the condition

---

III—FREDERICK W PRICE M D Lond F R S Edin

Physician National Hospital for Diseases of the Heart London

The subject of irregular action of the heart is of very great practical importance Formerly it was notoriously a source of perplexity and difficulty to the clinician A patient or it may be a candidate for life assurance or for an appointment, was examined and in the course of physical examination irregularity of the pulse may have been observed—with or without the usual physical signs of organic disease of the heart What significance was the practitioner to attach to the irregularity or the pulse in itself? It was known that this might on the one hand *signify definite and even serious impairment* or disease of the heart or on the other hand that it might be of no practical importance It was not possible however to determine the significance of the irregularity in any given case because there were no means of differentiating the types of irregularity or what any particular type signified The employment of the clinical polygraph and of the electrocardiograph has changed all this and the problem has been solved for we are now able to classify almost every case of irregular action of the heart into types, and we know what each type signifies I would at the outset emphasize two points—namely (1) Even *now notwithstanding* all that has been written on it, and the prominence given to the subject of late, there is not infrequently ignorance or a lack of appreciation of the recent advance in *knowledge of the* problem and its great practical importance (2) The work of elucidation having been accomplished by means of the clinical polygraph and the electrocardiograph it is not now necessary to employ either of these instruments in the vast majority of cases the use of a Dudgeon's sphygmograph being sufficient and in a large proportion merely auscultation This is of great practical importance to the general practitioner For example, by means of the aid of the stethoscope alone it is almost always possible to determine whether intermission of the pulse occurring during the course of acute infective diseases such as acute rheumatism, diphtheria and pneumonia is due to an extra systole failing to reach the wrist or to partial auriculo-ventricular block—a point of great prognostic importance

My custom is to classify all cases of cardiac irregularity apart from rare exceptions, into six groups (1) what is called sinus irregularity (2) irregularity due to premature contraction or extra systole, (3) irregularity due to heart block—whether sino auricular auriculo-ventricular or intra ventricular, (4) irregularity due to the pulsus alternans (5) irregularity due to auricular fibrillation and (6) irregularity due to auricular flutter To day we are concerned only with differential diagnosis significance and prognosis, and treatment and, in order to try to be of some practical help to the general practitioner I shall almost entirely confine my remarks with regard to diagnosis to the use of the stethoscope and of a Dudgeon's sphygmograph, *omitting all reference to the clinical polygraph* and the electrocardiograph May I emphasize the great advantage of auscultation at the apex over the other methods of physical examination in endeavouring to determine the type of irregular action of the heart —and the ventricular rate should always be counted at the apex

With regard to sinus irregularities it should always be remembered that while the condition is much more frequently met with in the young it may occur at all ages There is usually a definite relationship to respiration, and when irregularity of the cardiac action is found to be definitely related to respiration it is in all probability of the sinus type There is a variation in the length of the diastolic period of the cardiac cycle, while the systolic period remains constant and this can be detected by the stethoscope If a tracing of the radial artery be taken the intervals between the beat will be found to vary, but the actual variations are not numerous while the pulse beats are of equal or nearly equal, size There is no reason to suppose that sinus irregularity is either indicative of an impaired heart or that it adds to the gravity of any *diseased condition which may be present* so that this form of irregularity may be entirely disregarded

Extrasystoles are of great practical importance, they constitute one of the most frequent causes of irregularity of the pulse and may give rise to very disagreeable sensations It should be remembered that while they are of more frequent occurrence in the middle-aged and elderly they may be met with in the young They may appear at long or at frequent irregular intervals or regularly after each normal beat, or after every second or third, or more normal beats, or in paroxysms the last being an infrequent *cause of paroxysmal tachycardia* In most cases the pause which follows the premature contraction is abnormally long, being called the *compensatory cause* An extra systole may be so feeble that no wave is felt at the wrist so that there is simply an abnormally long pause resulting in an 'intermittent' pulse If a single extra-systole with its succeeding compensatory pause occur after every two normal beats, the pulse beat occur in threes the condition being known as pulsus trigeminus but if the premature contraction is so feeble that no wave reaches the wrist the pulse beats are paired (pulsus bigeminus) If an extra-systole occur regularly after each normal beat and the extra-systole fails to reach the wrist on each occasion, the rate of the arterial pulse is halved The commonest cause of intermission of the pulse, pulsus bigeminus, pulsus trigeminus, and halving of the pulse rate is the occurrence of extra-systoles On auscultation, in the vast majority of these cases, two heart sounds are synchronous with each cardiac cycle sometimes only the first sound very rarely is there an absence of both *sounds In the great majority* of cases a correct diagnosis of the existence of extra systoles can be made simply by palpation and auscultation especially the latter The differential diagnosis between intermission of the *pulse*, pulsus bigeminus, pulsus trigeminus and infrequency including halving of the pulse rate, *due on the one hand* to extra-systoles and on the other to partial heart-block, can be readily made as a *rule*, by means of palpation and auscultation, and will be referred to later It is sometimes very difficult, if not impossible to diagnose between extrasystoles occurring frequently and at irregular intervals, especially if of auricular origin from auricular fibrillation by palpation and auscultation alone but in such case a sphygmographic tracing is almost invariably sufficient

What is the significance and prognosis of extra-systoles? They indicate that a the time of the premature contraction some portion of the myocardium below the sinus is more excitable than the sinus This may or may not be due to some structural change in the myocardium it may, for example, be caused by poisoning of the heart wall without structural change The prognosis of extra-systoles is of great practical importance and there is considerable diversity of opinion on this question While it may be granted that extra systoles are of more common occurrence in the subjects of organic heart disease than in those who are not, and are more frequent in myocardial degeneration

than in valvular disease, further experience has not led me to change the opinion I expressed in 1911—namely, that when extra systoles are considered by themselves (that is, without reference to the conditions with which they may be associated) there is so far no evidence for supposing that they are either indicative of an impaired heart or that they add to the gravity of any existing morbid condition. Furthermore, while it is true that extra-systoles may precede the occurrence of other forms of cardiac irregularity, such as the complete irregularity associated with auricular fibrillation, it should be borne in mind that these might have arisen independently. The prognosis, therefore, should be based entirely upon the causal or associated condition.

With regard to treatment, this should be directed in the first instance to the causal or associated condition, the general health, and any existing cardiac failure, if present. I have never found digitalis or quinidine of any value for the irregularity itself. Bromides are frequently of benefit for the associated subjective symptoms, especially when there is irritability of the nervous system or insomnia.

Sino-auricular heart-block is a very rare condition, and the only remark I am going to make about it is that it may cause intermission of the pulse. Intraventricular block may give rise to gallop rhythm. The electrocardiograph is necessary for diagnosis. There are three degrees of auriculo-ventricular block: (*a*) there may be merely a prolongation of the interval which separates the commencement of the contraction of the auricle and that of the ventricle, each stimulus of the auricle reaching the ventricle, which duly responds; (*b*) the stimulus does not always reach the ventricle—in other words, the ventricle does not always respond to the stimulus from the auricle, and (*c*) a condition in which no impulses reach the ventricle from the auricle, so that the auricles and ventricles beat independently of each other. The first two of these are referred to as "partial heart-block," and the third as "complete heart-block." The first grade may give rise to irregularity of the pulse, on account of variations in the length of the intervals between the contractions of the auricles and of the ventricles. In my opinion this grade can only be recognized by means of the polygraph or the electrocardiograph. The second degree of heart-block may give rise to dropped beats, pulsus bigeminus, pulsus trigeminus, and infrequency, including halving, of the pulse rate. As already stated, the differential diagnosis between these conditions, due on the one hand to extra-systoles and on the other to partial heart-block, can readily be made, as a rule, by means of palpation and auscultation. In the former case a premature beat can be detected at the apex-beat, and on auscultation one or two heart sounds will, in the great majority of cases, be audible during the early part of the pause, because the ventricle has contracted, whereas in the case of partial heart-block, there will be absence of apex-thrust and of heart sounds during the pause, because the ventricle has failed to contract. When the ventricular rate suddenly falls to half its former rate, in all probability the case is one of 2 1 heart-block. In complete heart-block the pulse rate is slow, not infrequently being between 20 and 30 beats a minute, and usually not more than 36, though I have seen cases in which the rate has been considerably higher—even up to 62 beats a minute. It is sometimes difficult to distinguish between partial and complete heart-block without the aid of the polygraph or electrocardiograph. Most cases with a ventricular rate of 36 or under, however, are cases of complete heart-block. Also the presence of more rapid pulsations in the jugular veins than the rate of the radial pulse, and the presence of small waves occurring at regular intervals on the descending limb of the sphygmogram, afford help in differential diagnosis. In the opinion of some, faint muffled sounds may occasionally be heard during the long pause, due to the contractions of the auricles, although personally I have never been able to detect them. Some observers, too, have noted also an accentuation of the first sound, synchronous with the large pulsation in the jugular veins, when the auricular and ventricular contractions coincide. The occurrence of partial heart-block during the course of infective diseases is a sign, and may be the only sign, of myocardial involvement.

Digitalis and its allies are contraindicated in the first and second grades of heart-block, but not in complete heart-block, in which they may be given when there is dropsy or some other indication for their use. I have never found atropine, strychnine, oxygen, or amyl nitrite of any value in complete heart-block. Following Pheil and Parkinson, I have recently employed, with complete success, 5 minims of a 1 in 1,000 solution of adrenaline hydrochloride, administered hypodermically, in a case of Adams-Stokes syndrome due to complete heart-block.

By pulsus alternans is meant a condition of the pulse in which, while the rhythm is perfectly regular, a large beat and a small beat alternate. In the vast majority of cases it is necessary to take a tracing of the radial artery in order to recognize the condition. The prognosis appears to depend upon whether the condition is associated with tachycardia or not. In the former event it does not appear to have any serious significance in itself. In the latter, however, it is an indication of extreme exhaustion of the heart muscle. When the condition lasts only for a few cycles, this exhaustion may be only temporary, but even in these cases the prognosis should be guarded, when it is continuous, so far as my experience goes, death occurs within three years at the latest. It would be interesting to know whether the two cases mentioned by Dr. Wardrop Griffith were associated with tachycardia or not.

It is of the utmost practical importance that the variety of irregular action of the heart indicative of auricular fibrillation should be recognized, owing to its bearing on the diagnosis, prognosis, and treatment of cardiac affections. When auricular fibrillation has once set in, in the great majority of cases it persists for the remainder of life. This type of irregularity presents the following features: (*a*) It is continuous. (*b*) The irregularity is complete, the rhythm is irregularly irregular. In a sphygmogram it will be found that two beats of the same length or amplitude rarely follow each other. There is often no relation also between the length of a pause and the amplitude of the beat which follows it—that is, a short pause may be followed by a strong beat, or a long pause by a weak beat. There may be superadded ventricular extra systoles, occurring either isolated at irregular intervals, or, as is more usually the case, occurring regularly after each normal beat. In the latter event there is either pulsus bigeminus or coupling of the beats, or the premature contraction may be so feeble that no wave reaches the wrist, in which case the pulse rate is halved. This type of irregularity can usually be differentiated from the other types by palpation of the radial pulse and of the apex beat, and still better by auscultation at the apex. We may be reasonably certain of the existence of auricular fibrillation from the mere presence of complete irregularity of the pulse. In my opinion, the prognosis of auricular fibrillation depends mainly upon the causal or the associated condition, especially the integrity or otherwise of the myocardium, and whether any existing tachycardia can be controlled by digitalis medication.

On account of lack of time, I shall not deal with the subject of digitalis *versus* quinidine in the treatment of permanent auricular fibrillation (or of auricular flutter). With regard to digitalis, if auricular fibrillation is accompanied by tachycardia—whether there is mitral disease, aortic disease, or disease of the myocardium, the drug should be administered. With regard to dosage, my custom is to begin with 1 drachm of the tincture per diem, and to continue until there is anorexia, nausea or vomiting, diarrhœa, headache, an unduly slow pulse, or "pulsus bigeminus," or "coupling of the beats." The drug should then be stopped until these symptoms have passed away. In the great majority of cases the patient relapses, and the indication then is to find out what dose suits him best—that is the dose sufficient to control the action of the heart without at the same time giving rise to any toxic symptoms. One method is to begin with half the original dose, and this can be increased or diminished *pari passu* with the rate of the heart. Having discovered this dose it will be necessary, in the great majority of cases, for the patient to continue the drug for the rest of his life. In the course of time variations in the dose will be found to become necessary. The ventricular rate [illegible]

be watched Pulsus bigeminus is a danger signal and we should either stop the drug for a few days or diminish the dose I have used the method of massive doses introduced by Eggleston with success in a number of more urgent cases Intravenous injections of strophanthin are invaluable in still more urgent cases, or when the patient cannot tolerate any of the other preparations of the digitalis series of drugs by the mouth The results are the same as those following the administration of digitalis or strophanthin by the mouth, but are much more rapid, improvement in the general symptoms commencing within about two hours and becoming very pronounced six to ten hours later The injection should not be repeated within twenty-four hours, and then only in special circumstances and in a smaller dose, depending upon the ventricular rate Digitalis medication by the mouth may be commenced a day after the intravenous injection There is no evidence that the more recent preparations of digitalis are either pure substances or are more reliable than the tincture or the fresh infusion, both of which contain all the glucosides When auricular fibrillation is not accompanied by tachycardia no marked result usually follows the administration of digitalis

In most cases of auricular flutter there is a constant and uniform ratio between the auricular and ventricular rate, so that the rhythm of the arterial pulse is regular When, however as is not infrequently the case, the response of the ventricle to auricular contraction is at irregular intervals there is irregularity of the pulse rhythm, it may be even markedly so In some of these cases the sphygmogram may resemble that of a case from auricular fibrillation but if a sphygmogram from a case of auricular flutter be carefully studied it will be found that, even although the ventricular rhythm is very irregular the pulse beats measure out into groups of equal length whereas this is never the case in auricular fibrillation The diagnosis of auricular flutter is not infrequently impossible without the employment of the polygraph or the electrocardiograph indeed in some cases a correct diagnosis cannot be made with certainty even although the polygraph be employed an electrocardiographic examination being necessary I refer to the question of diagnosis without the use of these instruments under paroxysmal tachycardia in which the great majority of cases with regular rhythm or with pulsus alternans are due to temporary attacks of auricular flutter The same dosage of digitalis should be employed in cases of auricular flutter as in cases of auricular fibrillation with tachycardia, and the drug should be *continued until the full physiological* reaction is obtained After this, one of two plans may be adopted (1) The dosage may be lessened, and afterwards the administration of the smallest dose necessary to control the ventricular rate continued in the hope that the flutter may cease This plan is generally to be preferred, and I have had four successful cases of this kind within the last six months (2) Large doses may be continued in the hope of inducing auricular fibrillation, after which the administration of the drug is discontinued for some days in the hope of a return to the normal rhythm

A few words about paroxysmal tachycardia This term appear to be used in different senses I would suggest that it should be employed to denote a condition in which a marked acceleration of the cardiac rate occurs which commences suddenly and abruptly and without apparent cause lasts for a varying period, ceases suddenly and abruptly and is due to an abnormal rhythm—the stimulus for cardiac contraction, instead of arising at the junction of the great veins with the auricle, having its origin at an abnormal point The vast majority of cases of paroxysmal tachycardia are the result of (1) temporary auricular flutter with tachycardia, or (2) temporary auricular fibrillation with tachycardia Among other causes are paroxysms of extrasystoles We should consider the possibility of paroxysmal tachycardia whenever an individual is conscious of a marked increase in the cardiac rate or complains of attacks of palpitation, in either case occurring suddenly and without apparent cause, or suffers from dyspnoea on exertion, and other indications or cardiac failure coming on rapidly In some cases a correct diagnosis cannot be made with certainty even though the polygraph be employed an electrocardiographic examination being necessary The most important factors from the diagnostic point of view are (1) The commencement and termination of the attack of tachycardia The suddenness and abruptness of the onset and termination of the tachycardia is a characteristic feature—the maximum rate is attained within a few seconds and the return of the cardiac rate to what it was prior to the attack occur equally quickly, whereas in tachycardia associated with a normal rhythm the onset and termination are gradual (2) The cardiac rate A persistent rate of over 160 is almost invariably due to an abnormal rhythm, and a persistent rate of over 140 may be due to the same cause (3) The cardiac rate is not influenced by change of posture or other forms of physical exertion Within the last few months I have employed 5 grains—after a preliminary dose of 3 grain, to test for possible idiosyncrasy—of quinidine once daily in several cases of paroxysmal tachycardia, in the intervals between the attacks to prevent their recurrence, and it has been successful in each

---

IV.—W. J. TYSON, M.D., F.R.C.P.,

Honorary Physician Royal Victoria Hospital Folkestone

I THINK that it will interest this Section to be reminded that the subject or prognosis in heart disease was brought forward at the Annual Meeting of our Association at Brighton in the year 1886 I suggested to the collective investigation then in full work that this subject should be taken up and Sir Andrew Clark was the chosen spokesman to begin the debate

Within the last few days I have again read through the reports of this discussion and I can assure you it is strange reading Sir Andrew only dealt with valvular disease of the heart known to have existed over five years without causing serious symptoms, and in introducing the subject the author said that he must deal with it from a personal and empirical standpoint—a position which I intend to occupy this morning I may say in passing, in reference to the above debate that practically only the valvular side of heart disease was referred to Dr Frank Donald on of Baltimore was the only speaker who mentioned the wall being sometimes diseased The speakers including the late Dr Gairdner of Glasgow Dr Bristowe of London, and Dr Leach of Manchester drew attention to the points, which we now know, that rheumatic and choreic murmurs may and do disappear There were two significant expressions, which need to be repeated to-day (1) a case mentioned by Clark The patient felt ill only since he was told he had heart disease" and (2) by Bristowe "As to treatment, I am sometimes inclined to think that it is a pity there are physicians Many persons would lead a happy life enough but for them, it is quite time enough for persons to discover that they have heart disease when they begin to feel the effects of it"

The speakers did not consider the importance of the presystolic murmur in the same way as we do to-day, but they one and all—as opposed to Laennec—laid stress on the non-importance of most mitral systolic regurgitant murmurs, and also of many aortic regurgitant murmurs Clark's treatment was simple moderate diet, moderate exercise bowels attended to, work and encouragement Digitalis was more recommended in almost every case than it is to-day in other words its real action and proper place was not then understood, for as we know it slows the rate of the left ventricle without acting on the ventricle but through the vagus nerve acting on the supraventricular tissues

It is a long time since 1886—thirty-eight years—and this heart subject is again brought up at an Annual Meeting What changes or views have taken place during this interval? I am in a somewhat different position from many who are here to-day I have practised for forty-five years—hospital, private and consulting, more than this living in a comparatively small town I have had the opportunity, and I may say the advantage, of following up my cases I am purely a clinical physician and lay no claim to having known or worked the polygraph or the electrocardiograph although I have seen them used I have read pretty large

the heart literature, but I am giving you my own personal views and thoughts

In the first place, I do *not* think that my patients have suffered by my not having used the above instruments, but I must at once acknowledge that by these and other means our knowledge of the classification and diagnosis of diseases of the heart has been advanced One now recognizes sinus irregularity or respiratory arrhythmia, auricular fibrillation, extra-systoles or rather premature systole, heart-block, pulsus alternans, and tachycardia, but how far treatment has advanced in the same direction I think is very doubtful Looking back on my past cases I now recognize that I have seen examples of all the above conditions

It is forty years ago that I remember seeing a man of over 70 years of age suffering at intervals with what appeared at the time like an epileptic fit, his pulse varied between 30 and 15 I could find no disease to account for this variation, and of its origin or cause I knew nothing I found that by careful watching of the pulse I could tell when the fit would arrive, when this reached 22 to the minute the fit would occur Now, looking back, how plain the case appears!

There appeared about the same time in the BRITISH MEDICAL JOURNAL for 1879 and 1880 a series of letters on slow pulse, and, reading these again in the light of our present knowledge, I have no doubt that nearly all these cases were those of heart-block, yet not a single explanation of the cause is given

Again, take the case of respiratory arrhythmia, and consider how many young people have been condemned, and patients worried out of their lives, by being told that they had serious heart trouble and must rest from work and play I have had patients sent to me in ambulances from considerable distances, with full directions for permanent rest and continuation of drug treatment It requires courage and tact to get these patients up again and at work

The intermittent pulse we have all known for years—technically now called the premature systole or extra-systole—and have at last classed it in accordance with its true and correct value

We must all be particularly interested in auricular fibrillation, for we can now understand why many of our cases with a quickened pulse, say 120, with apparently no other disease to account for this rapidity, were benefited by digitalis, whereas other heart troubles were not so It is that in many cases of fibrillation we are enabled by experience to find out the exact dose of digitalis to keep the pulse at its proper rate—say 70

Tachycardia must have interested us all for many years and surprised us by being uninfluenced by rest and by exercise If I were asked what has been the greatest benefit conferred upon our patients during the last decade by men like Mackenzie and Lewis, I should say this, that in clinical medicine the effect of cardiac disease is to be estimated by the extent to which the ventricular action is affected, and the view that valvulitis is the central factor in heart disease has proved misleading In the words of Lewis, "The secret of successful prognosis lies in the actual tests of efficiency"

I had an interesting experience during the war in connexion with our own profession I was asked by the Government to examine all the doctors of Kent, Surrey, and Sussex between the ages of 40 and 55 with respect to their efficiency for war work One of my colleagues was a young heart specialist He reported unfavourably on some men as unfit on account of their supposed heart defects These men afterwards wrote to me—I suppose as being a Kent man and well known to them—saying that they were in large practice and working hard, and had never noticed anything wrong with their heart or their breathing until this army examination I replied that they should continue their work and think nothing about their hearts until some symptoms appeared, and even then, finding out their limitations, to go on working and live within these

It is said to me, and I feel sure that it is to you, to know how many people have been upset and depressed by this frequent heart examination It is quite time enough to know this when the heart begins to give trouble When breathlessness, pain, palpitation, giddiness, faintness, fainting, and fatigue appear, this is the time to think whether something can be done One would naturally then examine for oral sepsis, septic tonsils, chronic appendicitis, and acute, subacute, or chronic pulmonary lesions The one might influence unfavourably the prognosis in structural disease of the heart

I have watched aortic disease—regurgitant murmurs—for many years, and it has always appeared to me difficult to tell which of the cases are going to do well and which badly Of course it depends on the amount of the extra reserve power of the heart wall, and this, I take it, can only be gauged by testing in exercise Personally I have never seen a case of malignant endocarditis recover Dr Cotton says that a palpable spleen is usually associated with subacute infective endocarditis, but one hardly needs the presence of this sign to diagnose the above cases

In conclusion, the irregularities have been already mentioned, and are now well known As regards prognosis, a man's capacity for work is ascertained most certainly by putting him to work and by watching his reaction, after finding out what his limitations are he should live within them There are two diseases in which it is particularly necessary that rest should be maintained for some time—namely, rheumatic fever and influenza The two most important valvular troubles are the presystolic and the aortic regurgitant, but these vary greatly in prognostic value

I know of only one outstanding heart drug—digitalis—and even this one is practically confined to the treatment of auricular fibrillation, but I have found theobromine sodium acetate useful where there is cardiac dropsy

GENERAL DISCUSSION

DR FOSTER remarked that the irregularities of youth, and extra-systoles, were not now viewed so seriously, prognosis was good and treatment simple, especially in those cases where the over-anxious parent would give the child its freedom The condition of auricular fibrillation was on a different footing, inasmuch as there was often permanent damage done, thereby prejudicing a good prognosis Digitalis still remained their favourite drug and held its own Quinidine, however, sometimes acted when digitalis failed A young woman with mitral stenosis developed suddenly auricular fibrillation, was intensely ill, and cyanotic with much cardiac distress, quinidine was given and in thirty hours the patient was quite well She had a recurrence in eighteen months, owing to some alarming reports of the use of quinidine, digitalis was given, and the patient died in thirty hours He asked, what was the value of giving digitalis followed by quinidine? However optimistic one might be in heart cases, the outlook in cases of fibrillation was pessimistic, and those engaged in cardiological research should use all their resources to find out the cause of the condition, so that it might have treatment before the damage was done

DR HALLS DALLY (London) said they were all very greatly indebted to Professor Wardrop Griffith for the admirable and lucid manner in which, within brief compass, he had dealt with the salient features of the main types of cardiac irregularity, and to Professor John Hay for his views on the practical distinction between premature contractions and auricular fibrillation The essential difference, which Professor Hay had clearly pointed out, lay in the fact that the former possessed a dominant or fundamental rhythm while in the case of auricular fibrillation this fundamental rhythm was entirely lacking The more experience one had of electrocardiographic and polygraphic methods, the easier it often was to pick out the one class from the other without actual recourse to these methods at the time of clinical examination Now and again however, one came across a case in which the exact diagnosis became difficult or impossible without the useful aids It had been remarked by another [illegible] that he regarded prognosis in auricular fibrillation [illegible] always unfavourable When first the condition was described—and one had not then the opportunity of [illegible] out the subsequent history over a series of years—[illegible]

fibrillation was thought to be a grave condition, and to limit seriously the length of life In some cases it undoubtedly did so but with increased experience his own view was a far less gloomy one, since many patients with this condition lived for many years, and in the absence of other complications of gravity were capable of leading active and useful lives Digitalis was still their sheet-anchor, and he confessed that he found no other drug so useful in a large number of organic cardiac condition He found, however, that many practitioners were afraid of giving it, in the case of auricular fibrillation as well as in other cases, in the full dosage which was necessary to secure a state of partial heart block or in persisting in its use over a sufficiently long period of time Touching the effects of quinidine in cases of auricular fibrillation, their experience at Mount Vernon Hospital was that it should be avoided in the acute cases with rapid onset, and that it achieved most success in those of more chronic type This might probably be explained along the lines indicated by Professor Hay that the amount of toxaemia was usually proportional to the acuteness of the condition and that success was only to be expected when the toxic focus was first removed Premature contractions occurring in the absence of associated organic disease in individuals under the age of 40, on the whole carried a good prognosis when they occurred above this age he ventured to think that their significance was greater as indicating some defect which might prove to be more serious, although over 40 they were not infrequently met with He was in agreement with Dr Tyson in believing that at any rate in the case of anxiety neurosis grave harm was often done to the patient by his being told that there was something wrong with his heart

Dr G J Langley (Manchester) said that the more common cause of irregularity was probably produced by ventricular extra systoles, and these he divided into two groups The common one in which extra-systoles occurred might probably be regarded as physiological inasmuch as the usual complaint of the patient was that he could not get to sleep owing to 'the heart's bumping' The slowing of the heart which occurred prior to sleep doubtless gave a longer diastolic period during which there was increased opportunity for the ventricle to introduce an extra-systole Such cases showing extra systoles could be usually recognized easily, and it was found that the irregularity completely disappeared after sufficient exercise had been taken to raise the pulse rate There was, however, another group in which the extra systoles did not disappear on exercise, and these were prone to occur in patients past middle life One was tempted to believe that in such the irregularity might be due to changes in the myocardium That such changes were usual was shown by the work of Gosse in connexion with the alterations in the arterioles of the coronary circuit and for this reason they should be regarded as of serious import In connexion with the actual treatment of auricular fibrillation, it was possible that physicians had not given enough consideration to the question of the time occupied by a course of treatment and where time could be saved it was of natural help to the patient His own method had been to give a massive dose of digitalis tinct time according to the plan instituted by Eggleston and to follow this by quinidine according to the plan suggested by Emanuel of Birmingham, by which 6 grains of quinidine sulphate was administered every two hours until the pulse became regular, or half a drachm had been received By this plan the pulse speed was reduced by the digitalis as a preliminary and the regular rhythm was restored by the quinidine with the minimum waste of time Cases treated in this way had given results just as satisfactory as with the more prolonged method with the additional advantage of a considerably curtailed period of physical discomfort

Dr B H Pain (Southborough) referred to the problems that cases of cardiac irregularity presented in general practice

Dr E G Thomson (Bath) disagreed with Dr Tyson in his view that graphic methods were of no great value in general practice, on the contrary they gave valuable information about the condition of the heart muscle He asked for more information with regard to the dangers of quinidine, embolism was not infrequent in the ordinary course of cases of mitral disease was it more frequent in cases treated with quinidine?

Dr P W Veale (Leeds) protested against the habit of labelling patients as V D H and D A H He thought that no irregularity that had not been detected by the patient should be revealed He pointed out that auricular fibrillation did not occur in malignant endocarditis, and asked for an explanation

Lieut Colonel Longhurst asked whether anyone had had any experience of the use of convallaria which was used by Russian doctors to the exclusion of digitalis

Professor Hall said that the discussion had been interesting for the way in which it had brought together the point of view of the scientific man working from the scientific standpoint, and of the clinical man with the practical experience of the general practitioner It was the duty of a pendulum to swing Early in the last century the sounds of the heart were attracting so much attention that the pendulum tended to swing too far in their direction now perhaps it was swinging in the other direction Mistakes had been made in the things that were said to patient but the man in practice must say something and many things had to be considered in settling what was the right thing to say The term "weak" heart was to be avoided there was no "weak" pulse that meant anything as regards the heart

T Grainger Stewart M D, F R C P, President

DISCUSSION ON CERTIFICATION IN MENTAL DISORDERS FROM THE MEDICAL AND SOCIAL ASPECTS

OPENING PAPERS

I.—HENRY YELLOWLEES O B E M D, F R F P S G, M P C P Edin D P M
Medical Superintendent The Retreat York

I feel it an honour to have been asked to open this discussion Although I was largely concerned in the choice of the subject with which we are to deal, I will confess at once that it is one which is quite unusually difficult to review wisely or to discuss profitably It is, nevertheless, one towards which a remarkable amount of medical and public attention is being directed at present, and I hope that a discussion of some of the practical points connected with it may prove interesting and perhaps helpful here and there

The title of our discussion would seem to imply that the medical and social aspects of this question of certification can be readily differentiated and separately discussed This is very far from being the case, if the social aspect means or includes the legal one, which, of course, it must For our present purpose it will be most convenient to start at the beginning of this matter of certification from a medical point of view and to observe how soon and how repeatedly we come to close quarters with social and legal considerations

Let us begin, then with the statutory certificate and go directly to the essence of it, which is the practitioner's statement or his conclusion that the patient is "a person of unsound mind and a proper person to be taken charge of and detained under care and treatment" You observe that the patient's medical and social aspects are put together in this prescribed form of words and the one certificate has to cover both The patient is "of unsound mind" *and* he is a proper person to be taken charge of and detained and he cannot be one without the other

Now it is very easy to imagine a person who is distinctly of unsound mind and yet by no means necessarily "a proper person to be detained" Is the form of certificate faulty inasmuch as it makes no provision for such? "By no means," you say Such persons do not require to be

certified" Exactly The certificate, then, deals essentially with the patient's social relations rather than with his medical state It is primarily concerned with his fitness for detention, and not with unsoundness of mind The Lunacy Act is only interested in mental disease if and when it renders a patient fit for detention I do not mention this to condemn it, but because it has an all-important bearing on the course the practitioner must adopt when writing a certificate Before proceeding, however, we must look at the word "detained," whose acquaintance we have just made Derivatives of the verb "to detain" hold unquestioned pride of place in the Act of 1890, and are usually fittingly mated therein with the companion word "lunatic" Most intelligent physicians, and especially those interested in the study of mind and its disorders, abandoned the use of this latter word about the time when they discarded the bow and arrow in favour of the arquebus, and ceased to accept the evil eye as the exciting cause of "windy spasms" It still flourishes, however, in courts of law, in the Lunacy Act, in certain sections of the lay press, and, for an interesting though hardly creditable reason, among those self-appointed "reformers," who, like the House of Lords, "represent nobody but themselves and enjoy the entire confidence of their constituents" We need only say that the word, and those who use it, might be placed, with advantage to the general community, on a certain "little list" of which we have all heard

To return to the word "detention," it is clear enough, without going into fine shades of meaning, that it signifies a keeping against the will, an interference with personal liberty Here, again, you will notice that there is no glimmering of the idea that a person of unsound mind might conceivably be not only willing, but anxious, to stay under care and treatment There is no consideration given here to the fact (and it is a fact) that a considerable majority of certified patients are not "detained"—"behind the shut door," if I may borrow a journalistic catchword from the editor of the *Spectator*—but remain behind the open one, because they are unable or unwilling to go beyond it

All this boils down to the fact that while the insane man may be a sick patient to be cared for, the law is very much more concerned with him as a man who is—if we may put its phraseology into plain words—to be deprived of liberty because he is moonstruck

Now it is but just to say that all this is not quite so inexcusably and hopelessly wrongheaded as it seems at first sight—for which small consolation we do well to be thankful It is bad, shockingly bad, but one can see glimmerings of the reasons that prompted it The chief one of them is that there was one dominating idea in the minds of those who drew up the Act, and that was the safeguarding of the liberty of the individual

Now this is a great and noble thing, and it would ill become us to speak lightly of any measures framed to protect it There is no need to remind the average Englishman of his debt to those of his race who have gained for him the liberty he enjoys to-day, or of how precious a possession it is It must be said, nevertheless, that "lunacy" legislation is so utterly obsessed with this idea of safeguarding personal liberty that it ignores almost completely the facts that the insane are ill, that their illness often prevents them knowing what is best for them, and that the opinion most likely to be of value on the point would, in all probability, be that of a competent medical man The reasons in this are hardly relevant and would involve us in a study of the history of the Act, but they are connected with the state of public feeling at the time it was drafted, the personnel of those charged with drafting it, and the condition of things in asylums at the time

We must now consider what happens when the medical man has stated his conclusion that a given person is moonstruck and should be deprived of liberty The oft-repeated statement that the liberty of every individual in the country is in the hands of any couple of medical men is, of course, absurdly and grotesquely untrue, but if it were so, I imagine that the public would be, to say the least, no less safe than they are at present

A petition and statement are, as you all know, filled up by the responsible relative of the patient The latter, by the way, is invariably referred to at this stage of the proceedings as "the alleged lunatic" This petition, along with the medical certificates, is then presented to a county court judge, a specially appointed justice of the peace, or a magistrate, any of whom has power to make out an order for the patient's reception

This is by a very long way the worst and weakest part of the whole business of certification The number of reception orders signed by county court judges is probably negligible compared with the number signed by magistrates and specially appointed justices That these latter ladies and gentlemen bring to this important and difficult duty a sincere desire for the public good, much discretion, and the most absolute integrity, is questioned by nobody (except, of course, the "reformers" previously alluded to) My complaint against them is simply that they are as a rule quite ignorant of the detailed requirements of the law which they are called upon to administer

Many of you will be familiar with the results which follow this sad fact I know of reception orders having been signed in cases in which one or both of the medical certificates were missing, in a case in which the petition was addressed to myself instead of to the magistrate, and in a case where the petition had been omitted altogether! After such instances it seems almost an anticlimax to tell of a case in which one of the medical certificates was, by some strange lapse, dated November instead of June, of one in which the petition and certificates were dated as having been presented the day *after* the order had been made, or of one in which the magistrate offered to sign a blank reception order form without having seen any papers at all!

All these instances are true, and the patients arrive every week with similar glaring irregularities in their papers, but with the order, which is the legal authority for their reception, duly signed Now, in the strict sense, this may be said to be illegal detention, or, more properly, illegal or irregular admission, and you will notice that it is an entirely different thing from what is implied by that catchphrase as used by the "reformers" I will say, however, that not in one case in ten thousand is there "illegality" of any other type, and the public neglect of this really serious matter is a perfect instance of the pastime known as "barking up the wrong tree"

Irregularities such as those referred to have, of course, to be rectified at once, and every jot and tittle of the law fulfilled This difficult, worrying, and singularly unpleasant duty falls—and I hope you appreciate the irony of the point—upon those unfortunate and lawless persons, the Board of Control and the medical superintendent concerned

We hear much about "the system," and are told that medical superintendents are part of it, and that its distorting and besotting influence, acting upon their natural ignorance and prejudice, unfits them even to offer an intelligent opinion where the welfare of the insane is concerned Let us at least put it to their credit that much of their time is spent in helping to administer the law as it stands, and in correcting the errors, even though they be but technical ones, of those who surely ought to be (but never are) regarded as the very keystone of "the system," whatever—if anything—that expression may mean

We have now to return to the certificate from the certifying physician's point of view, and we notice that consists, or should consist, of a statement of facts upon which he bases his opinion that a patient is of unsound mind The law is not satisfied with a mere statement of the medical man's conclusions (a fact, by the way, which is not generally appreciated), it insists that he shall forth "facts indicating insanity" Facts personally observed at the time of examination must be included and facts communicated by others may also be added The doctor, therefore, is not made the sole judge of the patient's insanity While recording his opinion, he must place observed facts on which it rests before the representative of the law, who has every right to draw a different conclusion from them if he feels so disposed The person has to satisfy himself that the doctor's *opinion* is founded is the magistrate or justice, who, as we have

is a lay person with almost invariably no knowledge of medicine, and not infrequently only a very indifferent one of the law

We may profitably digress here to notice what I regard as the crucial difference between the procedure in England and that in Scotland Each country has, as you know, its own Lunacy Act, and, as regards ease of working, welfare of the individual, and general convenience, there is no room for question as to which is the better of the two The English law is hedged around with safeguards, but many of them have a sadly boomerang like tendency and bear hardly upon those for whose benefit they were introduced The Scottish law is very characteristically administered more with regard to equity than to legal *punctilios, and it has far fewer safeguards, but those it has* are cast-iron ones and are in the right place One of the chief ones has to do with the point under discussion In Scotland the petition and certificates are laid before the sheriff, who is the authority who issues the order or warrant for the patient's detention Now the sheriff is a trained (and salaried) legal official, high and lifted up, and has a short and effective way of dealing with undated petitions loosely worded statements and doubtful certificates He simply refuses to sign the order The papers are returned to the person who presented them and—sometimes—an indication is given as to where the weakness lies No exceptions are made and discussion is not invited on the subject Generally speaking, it may be said that once the sheriff has issued his warrant, the papers on which he did so could stand inspection down to the dotting of the i's, by the House of Lords itself

That is a digression, but it is one of the explanations of the comparative immunity from legal trouble in mental work in Scotland I can hardly think of a case in which papers were returned by the Scottish Board of Control as being out of order after the warrant had been obtained, whereas in England, I should say that many superintendents would count themselves happy if a month passed without such an occurrence

To return to the certificate We see from the foregoing that its main object must be to convince a layman that a given patient is insane in the legal sense—that is to say a proper person for detention Now with that main object clearly in mind, how can the certificate be most well-framed I am sorry to say that one answer, and one answer only, leaps to the mind, in the first instance The Jews of old, we read asked for a sign but never did Jew ask for a sign so persistently and eagerly as laymen and lawyers demand 'a delusion" 'Has he got delusion" and then one cry 'Give us delusions," they say, or we *perish*, or at least your certificate does" I am not prepared to deny that a delusion, properly so called is no doubt *prima facie* evidence of insanity, but probably the saddest thing in all mental work is the apparent impossibility of convincing the lay mind that the importance of a delusion may vary to an almost infinite extent in different cases On the one hand, a delusion may be of the most trifling significance, while on the other it may be the very centre and essence of the *whole* case All this unfortunately, is a closed book to the average lay mind and, in particular, to the average legal one One waits with hope, long deferred, for some medical witness who has the courage and is given the opportunity, to explain the matter, when asked absurd questions about delusions in a court of law

The extravagant, rambling statements of simple mania, the disjointed proclamations of dementia praecox, the depressed forebodings of melancholia, the grandiose ideas of general paralysis, the incoherencies of hallucinatory confusion, and the perverted reasoning and false conclusions of paranoia, are lumped in an ignominious equality as 'delusions" and that is the end of the matter From a medical and scientific point of view, of course the thing is almost too hopeless to talk about—but there it is After all one can see and appreciate here, as in other connexions *something* of the legal view, if one tries hard That John Smith said, "I am a white rabbit," is a good, practical sort of statement which can be put in evidence and cannot be argued about It suffices for the purposes of the law and avoids any necessity for bickering with mental specialists over matters of opinion and conjecture and surmise What the particular state of John Smith's mind was when he made that statement, what particular brain illness, if any, he is suffering from, or, indeed, why he ever made the statement at all, are matters about which the law is not disposed to worry, and why should it?

None the less I believe that we are doing a poor service to our professional and scientific consciences if we see out to make our certificate what I have heard described as a really 'truthy" one—full of all manner of "delusions," and yielding its fruit every sentence The great and in fact the only practical, test of sanity for the purpose of certificates is, of course conduct and the aim of every certificate should be to give a simple, but definite picture of *abnormal conduct on the part of the patient* That is the first essential, and the more clearly that your picture can also show this abnormal conduct to be due to illness, so much the better for your medical self-respect Now, as regards drawing the picture, some of us will tend to fine line work, with an abundance of detail while others will tend to go in for general impressions or sketchy outlines Those who can steer a middle course are the rarer—the writer—who can write good medical certificates Why this should be such a difficult art I do not really know I have often thought that the attitude of distaste, not to say fear and trembling in which many of us approach the duty has a good deal to do with it and that such an attitude is very rarely justified The duty falls into three parts The first consists of a careful and conscient ous examination of the patient, the second of asking and answering the question, "Do I consider this person to be unsound in mind, and, if so, why" and the third of expressing your reasons (provided you do consider the patient to be of unsound mind) in words which will convey a clear picture to a lay person, and cause him to share your conviction The more carefully the first two parts of the duty are discharged the easier will the third part be

This is not the occasion to discuss with you the cruder and more glaring errors in framing certificates into which many of us have fallen at one time or another Most alienists have a stock of illustrations of these, with which to embellish their after-dinner speeches, and I am no exception but it would be out of place to retail them here Errors are pretty equally divided in my experience, between the mistake of *giving too little detail*, which produces a vague and unconvincing certificate, and that of giving too much, which produces a verbose and confusing one "He is queer in behaviour" is as bad at the one extreme as is the following at the other "After shaking hands, I said, 'What day of the week is it?' He refused to answer at first, but after persuasion said, very slowly 'Tuesday morning,' the same being untrue, as it was Wednesday afternoon"

No rules for guidance can be given The best general principle in my view is to state the outstanding aspects of the patient's *mental condition* in a *fairly* general way, and after such statements give illustrations or examples from the patient's detailed symptoms Each case, however is a law unto itself and I hardly think you would desire that we should discuss the details of this part of our subject I pass therefore to the consideration of the social and legal disabilities consequent upon certification, apart from the actual loss of personal liberty

I repeat here, though without any great hope of being believed that only a comparatively small proportion of certified patients regard as a distinct grievance the amount of restriction of personal liberty which is necessary This amount, by the way, is infinitely less than the public imagine, and is far from being the greatest hardship suffered by the patient The others may be briefly summarized by saying that a certified patient forfeits practically all his ordinary social and legal privileges, with the solitary exception that if he makes a will it is not necessarily invalid Most of these are returned to him if and when he is discharged "recovered" while others—such as permission to visit America—are lost to him for ever While certified his signature is useless on a legal document of any description, except a *will, and many* of us are familiar with the difficulty and confusion which result and persist until the tedious and expensive process of

appointing a receiver has been gone through No doubt a strict application of the law is the only absolute safeguard against abuses and scandals in this difficult matter, but a little elasticity, such as the accepting of the signature of an intelligent patient on a cheque, dividend warrant, or power of attorney, in cases where all the parties are known, and fraud is out of the question, would save a great deal of hardship and expense in a vast number of instances

Let us glance, in conclusion, at the way in which the public generally regard certification There is no doubt that the present Lunacy Act, the general ignorance concerning mental hospitals, and the grave disabilities under which certified patients labour, have combined to give the public, and many medical men, an intense aversion to the whole proceeding, which they regard as putting an eradicable stigma upon the patient A majority of persons view it with an unreasoning terror and disgust, and will go to practically any lengths to avoid it

The chief cause among those named is undoubtedly the present Lunacy Act A full, critical discussion of it seems hardly within the scope of our title, so I have merely mentioned a few points which are intimately concerned with the process of certification While writing this paper, however, I accidentally came across the most acute and scathing criticism of the Act I have ever read, in a twenty-year-old number of the *Journal of Mental Science*, and I cannot forbear to quote two paragraphs

"The liberty of the subject bogey should be relegated to a legal limbo, and lunacy legislation should be based not on panic and prejudice, but on common sense and justice.

"The lunacy law wants reform on many points, but first it is necessary to persuade those concerned in legislation that the medical profession is not in a conspiracy to shut up all the community in asylums, but, on the contrary, is really desirous of doing good to the insane that the insane are not criminals, but sick persons needing the most careful, skilful, and tender treatment, especially in the early stages of the disease"

The article then proceeds to deal with the treatment of incipient insanity, and touches upon the last point I propose to take up At present, by Section 315 of the Act, any person who independently undertakes, for payment, the charge of an invalid against whom mental disorder can be even alleged, is guilty of a misdemeanour According to the law, if such a one can be certified he *must* be, and he may not be treated except as a patient of an asylum, registered hospital, or licensed house Taking this fact along with the public feeling regarding certification, it is obvious that the care of early cases—an extremely difficult problem in itself—is a hopelessly insoluble one in England to-day

Bad laws are badly obeyed, and the foregoing provision is no exception "Anything rather than certification," being the cry of the public, and the law being what it is, we have, to our shame, many a case of definite mental disorder undergoing "treatment," so called, in a "nursing home," by "a nerve specialist," who, whatever his qualifications, lacks the essential one of practical acquaintance with the insane Thus the very people for whom exists the modern mental hospital, with its facilities for treatment and its trained staff, are kept out of it

Real borderland cases are a different matter, but, candidly, I fear that the public is being misled on the subject Let it be said quite clearly that, generally speaking, a true borderland case does not become insane, a mild or incipient case is by no means necessarily a curable one, and the acute, recent, recoverable cases are, on the whole, far more abnormal in conduct and require far more specially skilled hospital care than the permanently and hopelessly insane Unfortunately, the very opposite views to the above, and many more fallacious ones, are held by, and are being taught to, the general public To quote once more

Uncertified care may be the best or the worst form of treatment and may bring either salvation or utter ruin to the patient Ignorance may be worse than cruelty and the incipiently insane person who is well fed well clad and tenderly neglected in the nursing home bed or the genteel back parlour until hope of recovery is lost, is really subjected to the most grievous neglect"

I have left much unsaid, and I have refrained from constructive criticism and suggestions I have thought it right in this opening paper merely to put before you some of the most striking points for thought and discussion which our title suggests

In a way I deplore the fact that no direct scientific or clinical interest is attached to this discussion, but the glory of our specialty is its wide scope, and we can at least justify the inclusion of this aspect of it by its intense social interest and importance, and its practical bearing on the welfare of the insane

---

II—G W B JAMES, *M C*, M D Lond, D P M Lond,
Resident Physician, Moorcroft House

When the general practitioner is confronted with a case of mental disorder he has a threefold task to perform He has to decide whether the patient is of unsound mind, and, if so, whether he should be certified If he decides that certification is necessary he has generally to overcome the family resistance to the advice he gives I should like to suggest a few clinical points which may be usefully borne in mind when the step of certification is in question

In the first place, what degree of insight has the patient into his own condition? Does he realize that he is ill? This is always an important consideration, for with a fair degree of insight it may be possible to avoid certification, and have the patient, if he be of the private class, admitted as a voluntary boarder Many such patients are still certified, though willing and even anxious to submit to suitable treatment, care, and control After insight comes the question of suicide Where a patient shows any evidence of being actively suicidal, certification is the wisest course Suicidal impulses occur in many depressed states, and it is well to remember that early cases of dementia præcox, especially young subjects whose school life has been unusually brilliant, are often liable to sudden, impulsive suicidal attempts, though there may be no apparent evidence discovered during examination There is the difficult case, which turns up from time to time, which is actively suicidal but not certifiable I mention this class of case because it would be instructive to learn the opinion of this Section concerning it I believe it is impossible as a general rule to certify a patient who intends to commit suicide unless there is other evidence of disorder of mind Next comes the question of danger to others Here there are some useful clinical signposts, not infrequently overlooked Ideas of persecution may or may not result in criminal conduct, but they are danger signals Many men live comparatively normal lives with vague ideas of persecution But the patient who discloses a firmly crystallized belief that he is being persecuted by one specific individual is a danger Most paranoid patients give us, clinically, warning of the approach of antisocial conduct by writing to the police or some public person, either for protection or to lay information against their supposed persecutor Persecutory ideas occur in many states—paranoia, dementia præcox, chronic alcoholism, epilepsy, and senile dementia being the most common The number of criminal assaults committed by senile dements with persecutory notions is surprising There is one form of these ideas of reference to which I would draw your special attention I refer to senile disorders, are generally directed against the chastity of the partner in marriage, and are a certain menace to the safety of the family and the public

I pass over the more acute states of excitement, confusion, and depression, where the state of the patient is obvious, and where certification is easy Many of the acute states are very transient, but I suggest that the best place for them effective treatment is a mental hospital, and that with increased access to and knowledge of these hospitals the public will adopt a changed attitude institutions for mental illness, and lose to a large extent its hatred of the admittedly unpleasant and cumbersome legal machinery at present associated with admission to treatment

With these few clinical suggestions I leave the practitioner, and propose to bring before you for discussion some of the difficulties of the physician in charge of a mental hospital The first deals with treatment

Having been duly certified as a person of unsound mind and a proper person to be placed under care, it is

surprising paradox to find our patient legally quite able to refuse the treatment which is deemed necessary by competent and expert medical men

Take the case of a successful and able business man, aged 40 years, admitted in a state of confusion. Examination suggests cerebral syphilis, with the prospect of excellent results from energetic antisyphilitic treatment. The gentleman, who has been making a sad mess of his business affairs for some weeks, stoutly refuses lumbar puncture, refuses the administration of salvarsan, and struggles violently if mercurial inunction be attempted. What is the right course to pursue? Such difficulties are, of course generally overcome in one way or another but no medical man is adequately protected against the possible consequences of forcing treatment upon a patient against his express wishes, however insane he may be. It seems reasonable, in a case where treatment is urgently necessary, and the friends of the patient are in complete agreement with the expert opinion advising the treatment that the patient's opposition should be overruled, and that the medical men carrying out the necessary technique should be securely protected against any possible legal action that might be taken by the patient.

The second difficulty to which I should like to draw your attention applies especially to those hospitals where patients are taken for payment. A patient, as you know, is detained by virtue of the judicial order, made by a specially appointed judicial authority and known as the "reception order." This remains in force for a year, and must then be renewed by a special report and certificate given by the medical officer of the hospital in which the patient is detained. For all practical purposes this is a renewal of the judicial order, and a recertification of the patient. It throws a heavy responsibility on the shoulders of the medical man—one which I venture to suggest is disliked and is certainly not wanted and does much to disturb the relationship between a doctor and his patient. In contrast to the Lunacy Act at present in force the Mental Deficiency Act of 1913 adopts a very different procedure and persons detained under this Act are seen at stated intervals by an independent practitioner and two visitors, usually justices of the peace, who decide between them as to the continuation of the order. Thus the medical officer of an institution where patients are received for payment has no part in the continuation of detention orders under this Act.

One of the most striking aspects of the whole subject of the care of the insane is the violent public feeling excited by any discussion of the subject. This will always be the case whatever Lunacy Act may be in force. Disorder of mind is still a profound mystery to the great mass of the public. It is in some ways comparable to the mystery of death. Think of the many defences erected by the community against the deep and instinctive fear of death. There are thousands of normal persons who will not pass a cemetery on a dark night. There is scarcely a village in Europe that is not erecting its magic stone emblem of propitiation to the spirits of those who died in the great war. Our patients touch similar deep and instinctive sources of feeling. One could recount at length the superstitions that have from time to time satisfied the public mind in its search for the cause of insanity. In this country a mental patient is still officially and legally described as 'moonstruck." We are all familiar with the panic caused by the rumour of an escape from the local mental hospital. Comparatively few years ago insane persons were treated with unbelievable cruelty, and that, let it be remembered with full public approval. In London itself a visit to Bedlam was a popular form of post-prandial amusement.

The community instinctively dislikes any departure from the normal and naturally persecutes its mentally afflicted: it criminals, and its scientific and social reformers. The happier lot of our patients to-day is due to the efforts of our own profession. But the public is still convinced that ill treatment is the natural treatment, and projects this conviction on to those of us who are engaged in this branch of medicine, believing eagerly the worst that is said of our work. Even legal luminaries regard "incarceration" in a mental hospital as the greatest of human ills, browbeat medical witnesses in court, and refer persistently to our nurses as "keepers." Our subject to-day is assuming a fresh importance in view of the recently appointed Royal Commission. It must be the aim of all doctors, both special and general, to evolve clear cut and constructive criticism of existing law.

GENERAL DISCUSSION

Dr. J. H. Thornley (Scarborough) said that he desired to thank the President and the officials of the Section for the compliment they paid him in asking him as a mere general practitioner to take part in the discussion on certification in mental disorders; and he felt some difidence in following upon the able and logical opening by so pronounced an expert on mental diseases as Dr. Yellowlees, but he hoped the Section would bear with him in his attempt to put forward some of the difficulties in this grave matter from the general practitioner's standpoint. He wished it to be understood that he held no brief for practitioners as a whole, but was merely speaking as one of them.

In the first place, although he considered that there was no reason to suppose that the trust reposed in medical practitioners and justices of the peace was abused by any negligence, yet the powers which the law conferred upon them were very serious, and the onus on the general practitioner was more than should justifiably be thrown upon him. Although he agreed to a great extent with Dr. Yellowlees that the oft-repeated statement, that the personal liberty of any individual was in the hands of a couple of medical men, was absurd, yet it was quite conceivable that the 'facts indicating insanity"—expressing the opinion of two medical practitioners who were possibly of very limited experience—and the order signed by a justice of the peace who's medical knowledge was *nil*, if not who's knowledge of the law was often decidedly limited, but who was rightly guided by the doctors' advice, ere to mean or legally depriving an individual of his liberty, and of attaching to him that stigma which—whatever we knew to the contrary—was still undoubtedly fixed upon him in the minds of the general public. Dr. Yellowlees had told them that in Scotland—and they had yet a good deal to learn from Scotland—a highly placed official the sheriff, acted in the place of the justice of the peace in England and satisfied himself that the legal requisite were correct, even to the dotting of the i's and the crossing of the t's. But much more so was it necessary that a highly placed mental expert, recognized and paid by the State, should sign and endorse a certificate justifying the medical opinion that the patient was of unsound mind and a fit and proper person to be detained as a lunatic. This he thought, would go a long way toward relieving the onus on the general practitioner, and convincing the relatives of the patient that by signing the petition and statement they were doing the right and proper thing. He was convinced that a patient, whether rich or poor, should have the benefit of the advice and experience of a mental expert—appointed by the State—who should be (if certification was decided upon) the signatory of one of the certificates.

They did not seem to be in the same position with regard to mental diseases as they were with regard to other medical and surgical cases, where they had the voluntary hospitals, staffed by the best medical and surgical men in the district, and where assistance in difficult cases was readily and willingly obtained even in doubtful infectious cases they always had the medical officer or health to give the benefit of his expert opinion and advice. With the exception of the large centres, there were no mental clinics where experts in mental disease could easily be obtained for advice and consultation. There were many medical men whose opinion might be perfectly sound, but who had not the aptitude for putting into correct phraseology the "facts indicating insanity observed by themselves," and it was a question whether the filling up of certificates was sufficiently taught at the medical schools. Dr. Yellowlees had told them how the layman and lawyer cry out for a delusion—but Dr. Thornley considered that there were not the only ones who did so. What a sense of relief it gave to be told by a colleague, when called in consultation with a view to certification that the patient had a

definite delusion Other conditions which worried general practitioners were those states of mental depression from innumerable causes—such as neurasthenia, brain fatigue, and financial, business, or domestic worries—when the patient saw his doctor, told him that he was "fed up" and felt so bad at times that he would like to "end it all," or that he was afraid lest he should lose complete control of himself and damage other people or take his own life These remarks were often made with a view to creating a sympathetic attitude on the part of the doctor and to impress him with the fact of how really ill the patient felt Although they might treat such remarks lightly, yet there was the lingering fear of a tragedy, the publicity of an inquest with the usual verdict of "temporary insanity," and the consequent damaging criticism of the medical attendant for not having realized the seriousness of the patient's condition

With reference to that group of cases including the insanity of toxæmias from acute infective disorders, traumatism, and the effects of drugs, alcohol, etc, were they justified in certifying such cases? They had to consider the benefit of the patient, who required skilled mental nursing and treatment under the best conditions, only obtainable in the best mental institutions, the undoubted slur which was absurdly but assuredly cast on anyone who had been confined in a mental hospital, together with the fact that the patient, if not in the acute stage, was certainly associated in the convalescent stages with other patients of a permanent type, such as those with dementia General practitioners were, therefore, divided in their opinion by the distinct benefits on the one hand, and the unfortunate social aspects on the other With regard to those difficult "borderland" cases where skilled observation was so essential, Dr Thornley considered that some method should be devised by which such patients could be temporarily detained This detention would automatically cease within a prescribed period, and thus give time for observation and reflection before a definite opinion was given He was sure that mental experts would be the first to admit the extreme difficulty in distinguishing the graver forms of neurasthenia and marked cases of eccentricity from some cases of insanity The general practitioner, the mental expert, the nursing home, or whoever was taking charge of the patient, would, however, need to be adequately protected against legal action

Dr Thornley summarized the difficulties and suggestions, which he had attempted to put forward, as follows

1 To lay the wraith of the "liberty of the subject" bogy by bringing in the aid of a trained alienist—a State official—to lift the burden from the shoulders of the general practitioner

2 The education of the general public to realize that insanity was a malady and not a social stigma

3 To obtain the aid of a highly placed legal official who would supervise the case and satisfy himself that the documents, etc, conformed to the law

4 The need for a more practical experience and instruction in the expression of the facts upon which the medical man's opinion was based, and to strike the happy medium between a too scanty, and what Dr Yellowlees had called a "too fruity," certificate

5 The fact that a delusion was so variable in its importance, although an obvious fact indicating insanity, yet it alone might not be a fact justifying certification

6 The constant fear of suicide

7 The justification or otherwise of certifying in cases of sanity of toxæmias, trauma, etc, when there was every reason to believe the cure would be speedy

8 The necessity of some very modified form of temporary detention for reflection and observation

Dr J I Russell (North Riding Mental Hospital) said that in the present form of certificate legal and social considerations almost completely overshadowed the medical aspect of the case The primary object of the certificate was to procure the patient's detention the question of treatment of his illness was rarely given a thought Neither the friends nor the doctor of the patient ever thought of sending him to a mental hospital until his conduct had made him intolerable at home From the legal point of view this was quite right, but he felt certain that it was to a large extent responsible for the vague fear and horror with which the man in the street viewed the subject of mental disease Dr Russell asked if they themselves were not encouraging this view They were joining in the popular cry—"At all costs save the incipient from certification," and to this end it was proposed that cases should be treated in general hospitals, often poorly equipped for this type of case—hospitals without verandahs and without gardens, and situated, perhaps, amidst the noisy traffic of the city He feared that this policy would only increase the stigma which was so unfortunately associated with the mental hospital, and he felt that it would be wiser to fight for the elevation of the mental hospital to popular favour, rather than to encourage a retrogressive movement which threatened to convert mental hospitals into homes for incurables Dr Russell believed that such a fight was possible, but not with the present form of certificate, and he suggested that the greatest good would result from the adoption of a medical certificate which would admit a patient to a mental hospital and there detain him for a limited period—three months if necessary—in much the same way that patients were detained in hospitals for infectious diseases At the end of this period, if not previously discharged recovered, the patient would either return home or a reception order would be prepared By this means he believed that cases would be received earlier, the status of the mental hospital would be raised, and the suicide of many incipient and recoverable melancholics would be prevented

Dr Russell then entered a plea for the rate-aided patient, considering that it was neither just nor reasonable that the certification of a poor man should be so much easier than that of a man of means Whatever purpose might be intended it was surely not achieved, since any patient, however affluent, might be admitted as a pauper and, without further certificate, be transferred to the private class, after which he remained as a private patient with but one medical certificate and without petition He considered that the same procedure should apply to private and rate-aided cases The poor patient had another grievance it was not an uncommon practice to remove him to a union hospital, ostensibly for treatment of his malady, but in fact merely to facilitate his transfer to a mental hospital, his certification and admission were arranged without either consulting or informing his friends Moreover, the petitioner of a private patient might at any time order his discharge, whereas the relatives of the rate-aided case had no such right It seemed unfair to deny to the next of kin of a rate-aided patient the rights and privileges enjoyed by the petitioner of a private patient

Dr Stanford Read (London) regarded insanity as really a legal term involving the necessity for control, insanity was to be distinguished from mental unsoundness In the minds of most medical men, however, the terms were largely synonymous The result was that the idea of commitment to an institution went hand in hand with mental disease In certification, the "facts indicating insanity" were highly debatable, and thus a medical man with practically no knowledge of psychopathology might commit a patient whose condition required no such step Thus, such symptoms as depression or suicidal ideas might be taken at an incorrect value It would be ideal, therefore, as Dr Thornley had said, to have in every local area an expert in mental disease who would be either entirely responsible for certification or be a co-signatory with the medical practitioner It would also be ideal if every mental case could be first placed in an observation hospital prior to certification The stigma attached to insanity was deeply rooted, and was only helped by the medical world speaking of "nervous breakdown" when the word "mental" should be used The public should be educated and familiarized with all the factors of mental hygiene, only in this way would the stigma gradually be removed In Gheel, in Belgium, where over a thousand certified insane patients were housed with the general population, and where they had more or less liberty—the system that had been in vogue for hundreds of years—the

had come about such a familiarity with insanity that it was viewed in a very different light from the usual one, and the factor of the stigma had sunk into insignificance.

Dr BEDFORD PIERCE (Leeds) said that the system of "voluntary treatment" should be greatly extended. The more it was used the less would be the need for certification. In spite of many recommendations, voluntary treatment was still impossible in any public mental hospital. It was perfectly true that few miscarriages of justice occurred under lunacy procedure. He personally had never known a patient wrongfully detained, and a legal commissioner had told him that he had known of only one case, and it so happened that privately he had heard particulars of this case which showed there was room for doubt. The record of the medical profession was extraordinarily good in this respect, and they could justly be proud of it. Yet they must not be content and silently ignore criticism. It was not that the asylum as a profession would suffer, but that there was grave danger that timely treatment of their patient would be delayed. The Harnett case disclosed a painful ignorance of mental hospital administration and the attitude of counsel and even the Bench, towards medical men engaged in psychiatry left much to be desired.

Dr. Bedford Pierce submitted that the procedure in respect of compulsory treatment in recent acute cases—such as acute melancholia following confinement and delirium during the course of convalescence from acute infective disease—should be different from long-standing cases. There was the case of a man suffering from depression who tried to throw himself out of a railway carriage window and was certified; he recovered in a week and found himself deprived of his post as managing director of his company in accordance with the articles of association. Cases such as these needed skilled care upon some temporary basis without certification. He considered that certification could be deferred safely provided (1) there was no concealment, and (2) the hospital or place of treatment was properly equipped. Privacy without concealment could be secured by a system of notification accompanied by medical statements and reports. Much had yet to be done to provide proper conditions available to all. At least three provisions appeared to be essential, and all unfortunately involved more expense. (1) Adequate medical service (not one doctor to 500 patients). (2) A skilled and trained nursing service. (3) Provision of gardens, occupations, interests, and the exclusion or the degraded chronic insane. If in every area suitable hospitals were provided, such could be affiliated to the general hospital and where medical schools existed they would become centres for teaching psychiatry. A great step would thus be taken towards providing early and more effective treatment, and in reducing the need for formal certification.

Concerning the present procedure of certification, Dr. Bedford Pierce submitted the following criticisms. (1) The present magistrate's order was of little value as a safeguard. He agreed with Dr. Yellowlees that the Scottish method of a sheriff's order was better. The order should be given by a trained lawyer with a fixed address and definite hours. In case of doubt he would be authorized to call for expert assistance. Any inconvenience or danger from delay could be met by an elaboration and extension of the Urgency Order. There need be no special haste about the Reception Order if the patient recovered before it was obtained so much the better. (2) The procedure in pauper and private cases should be the same. The fact that the patient was an artisan's wife did not justify any less care. He advocated two certificates in all cases. (3) There seemed no reason why the doctors should be obliged to see the patients separately. (4) It had been suggested by Dr. Tromley that one of the certifying doctors should be a specialist. He was doubtful, however, whether it was wise to split up the profession.

As a subject for discussion, Dr. Bedford Pierce suggested in respect to complaints of improper detention the appointment in each district of a legal referee, who would be entitled to call in expert advice and see documents. The deprivation of civil rights was a grave matter and as a profession they should readily welcome appeal to a legal authority. Conflict would no doubt arise, and patients might be recommended for discharge undesirably, on the whole, however, the burden on medical men in charge of the insane would be lessened. The scheme might work out as follows. A patient was released and complained of his detention. It would be the duty of the medical man in charge to give the particulars as to how he could apply to the referee (somewhat akin to the form which was at present supplied for appeal to a magistrate). The referee would take such steps as he considered necessary to satisfy him that the patient was rightly detained; if dissatisfied he would report to the Board of Control for decision. This would necessarily mean the decentralizing of some of the work of the Board of Control, but it would not reduce their responsibility in those cases that could not be settled locally.

In conclusion, the speaker urged the following points. (1) The voluntary treatment of patients should be facilitated in every possible way. (2) Temporary detention without certification in recent acute cases should be permitted. (3) Effective treatment should be secured for all patients, poor as well as rich. (4) A legal referee empowered to call in expert advice in difficult cases should be appointed in every district. (5) Finally, the responsibility of initiating treatment necessarily thrown on the medical profession should be accompanied by effective legal protection, but every patient if aggrieved, should have a right of appeal to a legal referee.

Dr JOHN MILLS (Ballinasloe, co. Galway) expressed his entire agreement with the chief points of reform indicated by Dr. Bedford Pierce. He considered that the most urgent reform needed was that the class referred to by lawyers as "pauper patients" should be allowed admission, under proper safeguards, to district asylums on the same conditions as "voluntary boarders" were admitted to private institutions. He could recollect many patients with incipient insanity who had come to him asking for admission under the present law he was compelled to refuse. Dr. Mills also desired to draw attention to the great reluctance of juries to find anybody insane no matter how strong the evidence and suggested that temporary detention on the certificate of an official similar to medical referees under the Ministry of Pensions would give the general public more confidence in mental hospitals.

Dr DAVID BLAIR (Lancaster) said that it was distinctly unfair that the whole onus of certification should be thrust upon the family physician. He considered that all patients—private and rate-aided class alike—should be certified by two medical men, one being a specially appointed mental expert *and the other the patient's usual medical attendant*. The importance of the medical certificate being a statement of facts and not a mere expression of the doctor's opinion, was *not sufficiently realized in practice*.

Dr. C. WORSTER-DROUGHT (London) emphasized the importance of remedying the anomaly that a patient certified as of unsound mind was legally able to refuse all necessary treatment. Certification therefore did not imply compulsory treatment. He had a case of one of cerebral syphilis to which Dr. James had referred and entirely supported his observations. The matter could be adjusted by the insertion of a treatment clause in the medical certificate or if this were impracticable from the legal standpoint by using an additional certificate authorizing necessary treatment and protecting the physician from legal action as regards the question of certifying a patient merely on the reiterated threat to commit suicide. Dr. Worster-Drought was of the opinion that in the majority of such cases certification was unjustifiable. He remembered an instance which occurred while he was engaged in neurological work in the army during the war. A recruit was admitted to hospital with the history that he had attempted to drink carbolic acid. While in the observation ward the patient repeatedly announced his resolve to commit suicide, but showed no other symptoms. He was not unduly depressed nor did he exhibit any disorder of conduct. In due course he was certified about four years

later, when the war was over, the patient sought out Dr Worster-Drought, and among various threats accused him of ruining his life by causing his certification, he said that not for one moment had he ever intended to commit suicide, but that he had merely acted the part to escape military service Some months later, however, he was again certified by other physicians, and was still in a mental hospital

Dr Worster-Drought considered that a defect in our social system was that between the general hospital and the county mental hospital there were no institutions to which a patient of the so-called "pauper" class could be admitted The general hospital was not suitable for, and usually did not admit, either borderland cases or those suffering from the milder forms of insanity, there was no other course but certification Some cases were admitted to the special hospitals for nervous diseases, but these institutions did not really desire such cases, nor were they entirely suitable What to do with the mild and borderland cases whose means were slender and those of the hospital class was an ever-recurring problem The position could be met only by the foundation of special institutions similar to the Maudsley Hospital, or by the admission of voluntary boarders to the county mental hospitals, the latter course, however, was not without its objections

A COMPARISON OF THE EFFECT OF THE LONDON CLIMATE ON CAPTIVE ANIMALS AND MAN

BY

N S LUCAS, M B,

PATHOLOGIST TO THE ZOOLOGICAL SOCIETY OF LONDON DEMONSTRATOR OF COMPARATIVE PATHOLOGY AT THE MEDICAL SCHOOL, UNIVERSITY COLLEGE HOSPITAL

It had long been felt that there was some correlation between the weather and the number of deaths occurring among the animals living in the Zoological Society's Gardens, but there had never been any attempt to work out the actual figures This was probably due to the difficulty of obtaining accurate figures of the climatic conditions prevailing in the neighbourhood of the Gardens, the figures derived from Kew naturally would not apply However, from 1919 records have been kept at the Royal Botanic Society's Gardens, and as these are situated within half a mile of the Zoological Gardens, it would appear that these could be applied to the Zoological Gardens without introducing any serious error I wish here to acknowledge my indebtedness to the curator, Mr J L North, for the loan of all his records, which has made this analysis possible

In view of the larger numbers of small birds kept in the Gardens, and the frequent difficulty in giving an accurate diagnosis of the cause of death, it was not justifiable to attempt to work out figures for birds The conditions prevailing in the Reptile House also seemed to place the inhabitants somewhat outside the influence of the weather It was resolved, therefore that only mammalian deaths should be examined For this purpose all deaths due to accident or the attacks of cage companions were excluded The atmospheric conditions which appeared to have a bearing on the matter were the following

1 Maximum temperature in the shade The temperature in the shade was selected because all the animals have an opportunity to get into the shade should they wish it

2 Minimum temperature of the air This was chosen rather than minimum temperature of the grass, for the reason that in cold weather all the animals have a shelter—not necessarily heated, but enough to keep them from the extreme of ground temperature The warming of houses would seem to introduce a fallacy in the use of external temperatures, but in most cases a change of external temperature, if of any magnitude at all, affects to some extent the level of temperature in the houses

3 The total rainfall per month

4 The number of days per month in which the wind blew from the quarter between the north and the east This was included because it had been observed that the number of deaths seemed to increase when the wind was in that quarter

5 Total sunshine per month

6 The number of days per month on which fog occurred

7 Percentage of moisture in the atmosphere, saturation being taken as equal to 100

8 Total deaths per month

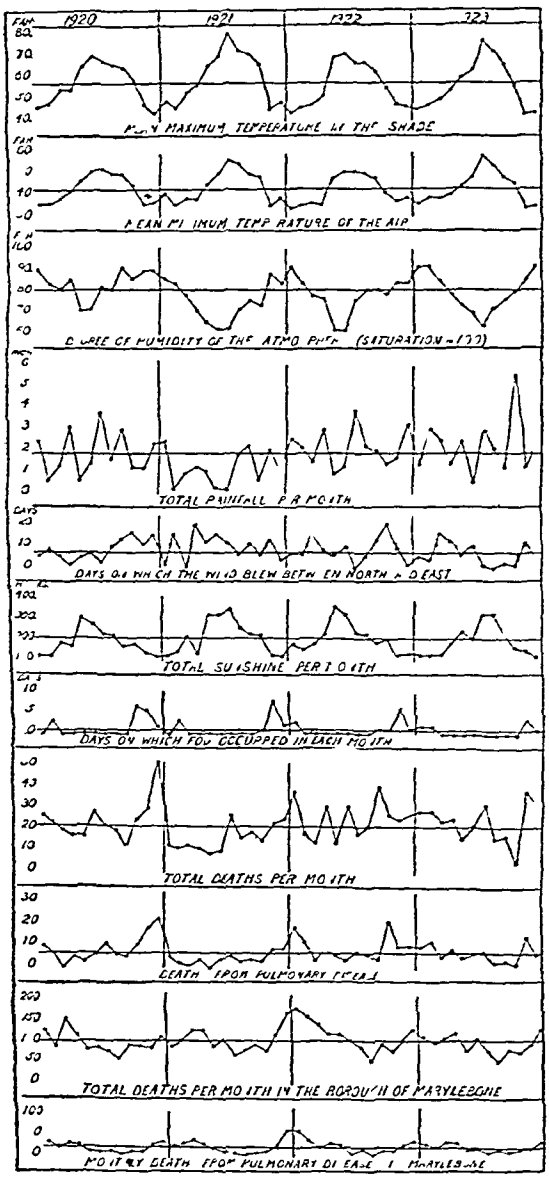
9 Total deaths from pulmonary diseases other than pulmonary tuberculosis

Further, it was felt that it would be of considerable interest to show a comparison between the deaths of the higher and lower mammals Figures were taken from the deaths occurring in the Borough of Marylebone excluding those due to accident or suicide Also a chart is given here for pulmonary disease in the same area Marylebone was chosen as being the borough in which the greater part of the Gardens is situated For these figures I have to thank Dr Charles Porter, B Sc, medical officer of health for Marylebone

A short explanation is also required of the charts themselves The four years taken are 1920, 1921, 1922, and 1923 These are indicated by the vertical black lines Each of the twelve black dots in the division represents a month The numbers are totals except in the charts of humidity and temperature, when the monthly number is the mean of the daily readings for that month The monthly figures for the four years then added together and divided by 48 give the mean for the four years, which is indicated by the horizontal black line running the length of each chart If the charts are then placed vertically in order, with the vertical black lines corresponding, the deviations from the mean occurring in each month can be read with ease

Turning first to the charts of total deaths in the Gardens, it is seen that the number of deaths is, as a rule, above the average in January, and then falls gradually, with a rise in June and July, after which it falls, to rise again in the late autumn There is not, however, any great regularity Yet it can be said that the months of August and September are the healthiest

There is one year which is worthy of special note—namely, 1921 This was a year in which there was a remarkably fine spring, summer, and autumn The monthly total of deaths is below the average through a larger and more unbroken period in the year than is shown in any of the other years In fact, the only months in which the total is above the average are July, November, and December, and in November it is only just above—that is, 23 as compared to 22 5 That July, which was the hottest and sunniest month of the year, should be the month with the highest number of deaths—namely, 27—may appear remarkable but the drought brought with it a great deal of dust and also tended to cause decomposition of food, with attendant diseases of the alimentary tract



Human mortality, on the other hand, was not unusually low during 1921 The monthly total of deaths was only below the average during six months, and in December it reached a total only second to that of January, 1922, which was the following month Another reference will be made to this later

The pulmonary disease charts of animal and human show a much closer relationship, and both run in a more regular fashion There is a rise in November and December which reaches its highest point in January It falls during the spring, to remain at its lowest during June, July, August and September The year 1921 shows an abnormality, which is especially marked in the animal deaths Here the monthly deaths for the first ten months of the year were all below the average, while those for November and December were only 9 for each month, the average being 7 On the other hand, the human deaths only showed two months with totals below the average

Having pointed out that these rises and falls exist it is now appropriate to examine the other charts and to see what deviations from the normal can be found to have existed during those months in which there was a deviation from the normal in the death totals

Probably the first condition to occur to the mind of the investigator with regard to climate and the deaths of animals is temperature As would be expected, the charts of maximum and minimum temperature corre-

very closely When the mean monthly maximum drops, the minimum follows it, although there is one striking difference, which is that the deviations from normal for the maximum are far greater than those of the minimum The former ranges from 45° to 80° I , while the latter only ranges from 35° to 58°, so that the range of the one is more than twice that of the other The greatest deviations of minimum temperature occurred in February, 1921 and January, 1922 In February, 1921 (temperature 36°), the

to all deaths were 13—that is 9 below the mean while in January, 1922 (temperature 35°) the total deaths were 38—that is 16 above the mean The deaths from pulmonary disease were 3 below and 12 above respectively The figures for Marylebone were exactly average—that is, 110 for February 1921 while for January 1922, they reached 270 —that is, 160 above The pulmonary deaths were 7 and 30 above the average in these two months

These figures have been chosen as examples, but it can be seen from examination of the charts that the death figures and those for temperature do not correspond It is true that in the warm summer months the deaths are fewer than in cold winter ones, but, as the example taken shows, in two months in which the average monthly minimum temperature differs only by one degree, the difference in the death totals is very marked

There is another aspect of temperature which might easily be considered responsible for a large number of the deaths among exotic mammals this factor is the rapid changes in temperature from day to day, the existence of which in *the English climate*, is a *by*word To examine this a chart was made of the daily temperature , maximum and minimum, for two years, and beneath it a chart of the daily deaths. In spite of the fact that a drop in temperature of 10° in twenty four hours was by no means uncommon occurrence the death rate seemed absolutely unaffected by such changes In fact, *the one had so little bearing on* the other that there was no need to reproduce any of the charts It is not unnatural that this should be so, when the conditions in many semi tropical parts of the world are considered, where the fall of temperature at sunset is far greater and more rapid than it is here It is necessary therefore , to search elsewhere for a cause and the next points to examine are rainfall humidity of the atmosphere, and the direction of the wind

It will be simplest to compare in tabular form the two months which were previously used to point out the small influence of low temperature when considered alone These months were February 1921, and January, 1922

	February 1921	January 1922
Total deaths	13 below normal	16 above normal
Pulmonary deaths	5 below	12 above ,,
Total human deaths	Normal	30 above ,,
Pulmonary human deaths	7 above normal	30 above
Humidity	3% above	11 above ,,
Days of wind N to E	7 above	1.5 below ,,
Total rainfall	1.8 in below	0.7 in above

This is a very nearly perfect example of the importance of a warm moist dry atmosphere in health The only point in which there is a failing is that there were fewer days of northerly and easterly winds in January, 1922, than in February, 1921, but, as will be shown later, these unfavourable winds appear only to have influence when accompanied by rain It is interesting to note that the maximum temperature of February was only two degrees higher than that of January

Choosing the deviations in another way, December, 1920 provided the greatest total of animal deaths during the four years, and also the greatest total of pulmonary deaths, while October, 1922 gave least in total deaths and a very small pulmonary aggregate

	December 1920	October 1922
Total deaths ...	30 above normal	17 below normal
Pulmonary deaths ...	16 above	5 below
Total human deaths	10 above	13 below
Pulmonary human deaths	12 above	5 below
Humidity	9% above	1% below
Maximum temperature	10 below	1 below
Minimum temperature	6 below	2.5 above
Days of wind N to E	7.5 above	7.5 below
Rainfall ...	0.5 in above	0.8 in above
Sunshine ...	60 hr below	90 hrs below

Contrasting these two opposites it can be seen that in December the weather was unduly cold and there was a northerly wind There was only a slight excess of rain over the normal, yet the humidity was 9 per cent above the normal In October, a favourable month, the minimum temperature was above the normal, and the maximum only slightly below it The days of northerly winds were as much below the average as above it in the other month, but

the total rainfall was tremendous, and the humidity 1 per cent below the normal This would support the argument that rain without cold winds is harmless, while the converse also applies The human deaths correspond also, but, owing possibly to the different modes of life of acclimatized humans and unacclimatized wild animals, the difference is not so marked

Looking at the problem from the point of view of the average number of deaths in a month, July, 1920, has been chosen as showing an exact average total of deaths, and it is notable that there is no great deviation of wind, rainfall, or humidity, and that the deviations of the two former balance each other

July, 1920	
Total deaths	No deviation
Pulmonary deaths	4 above normal
Total human deaths	20 below
Pulmonary human deaths	5 below
Humidity	1% above
Maximum temperature	10° above
Minimum temperature	10° above
Days of wind N to E	5 days below
Rainfall	1 9 in above
Sunshine	20 hours above

There are two more factors which must be considered—namely, fog and sunshine With regard to the former, one cannot help feeling that, in Regent's Park at all events, the prevalence of fog was not really very great in these four years There have been only forty-one days on which fog has occurred in the whole of them, and on very few of these has the fog persisted throughout the day It is true that the number of deaths is greatest in those months in which as a rule fog occurs, but rain and north-east winds are also prevalent then, and in a much greater degree Of much greater importance is sunshine, or rather it is to be feared the absence of it, for the daily average of sunshine is but three hours out of the twenty-four In the winter months it is approximately one hour a day It is unnecessary to discuss here the action of sunlight in the prevention of disease That it plays a very important part is now generally accepted There is, however, one point which will bear emphasizing, as being new, and that is a possible difference in the effect of sunlight on man and animals To see this it is only necessary to look at the charts for sunshine and human and mammalian deaths for 1921 Reference has already been made to the good health of the animals during this year, but, whereas the total of *deaths remained low* among the animals in November and December, among the humans the total for the same months rose to a great height In fact the number of deaths in December was the second highest recorded in the four years, the largest being that of the January following It would appear, therefore, that the lower mammals might be capable of storing up the sunlight and using it to increase their disease-resisting powers more satisfactorily than can the human

The period over which these statistics extend is somewhat too short for any very strong conclusions to be drawn, but they are certainly suggestive of the two following

1 That a dry cold atmosphere is not harmful, nor is a warm *moist one*, but a cold damp atmosphere is most deleterious both to the higher and lower mammals

2 That while sunshine is beneficial to both, it would apparently have a more lasting effect on the lower mammals

REMOVAL OF PART OF A SAFETY-PIN FROM THE BRONCHUS OF A CHILD BY PERORAL BRONCHOSCOPY

BY

D A CROW, M B , Ch B Edin ,

ASSISTANT SURGEON SUSSEX THROAT AND EAR HOSPITAL, BRIGHTON

The following case illustrates the relative absence of signs and symptoms which is almost characteristic of the aspiration into the air passages of a metallic *non-obstructive* foreign body

Peter C , aged 2 years and 10 months, had been playing with a damaged safety-pin on May 18th, 1924 The mother noticed that he had a slight attack of coughing lasting only a few moments, and she was unable to find part of the safety-pin Little more was thought of the matter, for there were no further symptoms beyond a slight loss of appetite, but after three or four days a very slight cough developed, just sufficient to give the mother a little uneasiness and cause her to consult the doctor, who, even in the absence of physical signs, fortunately decided to send the child to hospital for an *x-ray* examination

The child was admitted to the Royal Alexandra Hospital for Sick Children, Brighton, on May 24th, the honorary radiographer, Dr Burrington Prowse reported on the same day the presence of part of a safety-pin in the right bronchus It was lying obliquely at the level of the second to the fifth dorsal vertebra, safety-catch downwards, and tilted one inch from the middle line, the spring and pin portion were fortunately missing

Radiogram of part of safety pin in right bronchus

The child's condition was normal apart from a slight occasional cough, and the only physical sign present, and that an equivocal one, was a trace of deficient expansion on the right side

On May 25th the child was starved of fluids for five hours and given 1/200 atropine in order to keep the bronchus as free as possible of secretion Under chloroform anæsthesia the larynx was exposed with a laryngeal spatula through which a 5 mm bronchoscope was passed into the trachea The upper end of the pin, not yet blackened, was seen just above the carina, and was grasped with slender Paterson forceps A little manipulation served to release the impaction of the safety catch, which was caught on the junction of the upper lobe bronchus, and the pin was then withdrawn, together with the bronchoscope, to the level of the rima glottidis, into the axis of which it was rotated, and then removed The bronchoscope was in use for four minutes, and no post-operative oedema developed For four days there was slight hoarseness, and the child left the hospital in a week

An experience such as this emphasizes the need for vigilance in dealing with cases in which the presence of a foreign body is suspected, whether or not presenting symptoms, and the advisability of a radiogram in all cases It also emphasizes the fact that peroral bronchoscopy is a satisfactory means of dealing with such cases, which should completely supplant the old method of bronchoscopy through a tracheotomy wound

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL

POST OPERATIVE THIRST

I venture to suggest the following simple means of relieving the thirst and dryness of the mouth and throat which follow abdominal operations It consists in spraying the throat and mouth with a solution of boracic acid gr 10 to the ounce of water, slightly acidulated by the addition of a little lemon juice The spray is cooling and cleansing in its action and reaches all parts of the mouth fauces and pharynx which neither gargling nor rinsing of the mouth can do without considerable exertion and practice they are practically impossible in children Spraying requires no exertion on the part of the patient beyond opening the mouth and can be applied in whatever position the head may be resting The liquid used can be made very cold by keeping the bottle on ice or hot by placing it in a bowl of hot water I have found the cold spray to be the most gratifying to the patient the spray can also be used to great advantage in fevers and sore throats

Aberdare

TUBERCULOUS CERVICAL GLANDS

With reference to the article on tuberculous cervical glands by Mr R Davies Colley C M G F R C S in the Journal of August 16th (p 259) I would like to mention a method which has been used by me for the treatment of single suppurating tuberculous glands before or even when they have involved the surrounding tissues to a slight extent, but before a sinus has been formed

As soon as fluctuation is present in the gland the skin is sterilized and a suitably curved surgical needle carrying a stout linen thread is made to transfix the abscess It the gland is tending to point to the surface the site of exit is made at that spot—the points of entrance and exit being kept as far apart as possible The ends of the coarse linen thread suture are tied in a knot so that a loose circle of thread is left passing through the gland A dry dressing is then applied

The contents of the abscess cavity drain out by way of the linen thread suture and every day the loose circular suture is moved either a little forward or backward to prevent it adhering The skin is painted with tincture of iodine once daily, and dry dressings applied as required The pus is allowed to drain out in this way till discharge ceases when the suture is cut and withdrawn

The main advantages of the above method, where applicable are the ease of application and that no resultant scar is left

F A E Silcock, M B D P H,
Medical Superintendent City of Leicester Isolation Hospital and Sanatorium

A CASE OF GENERALIZED VACCINIA

The case here recorded seems of sufficient interest to warrant publication

E W J a general labourer aged 44 was admitted as a recurrent case of melancholia to the Kent County Mental Hospital on July 23rd 1924 On July 29th vaccination was performed on the right arm in the region of the insertion of the deltoid On the morning of August 4th four pale papules appeared surrounded by a reddish area which daily became umbilicated purulent vesicles on August 6th accompanied by considerable swelling and inflammation of the whole limb In the evening of this (the eighth day after vaccination) a distinct vaccinia rash appeared on both arms the temperature rose to 102° and the patient complained of nausea and headache By midnight the rash had spread to the whole of the body excepting the face and the temperature (axillary) registered 103 4° The pulse rate was 90 and the respirations 20 No enlargement of glands could be felt On the following morning the temperature fell to 100° and the rash had begun to disappear in the evening the temperature was 98 4° There has been no further pyrexia or reappearance of the rash

I am indebted to Dr M Abdy Collins, the medical superintendent, for permission to publish the notes

G T Baker, M C, L M S S A,
Assistant Medical Officer Kent County Mental Hospital Chartham Down

LARGE OVARIAN CYST AND GALL STONES

This case appears to me to be of sufficient interest and rarity to justify publication

A married woman aged 56 was referred to me by Dr Rowland Llanadhairn on April 22nd 1924 and was admitted to hospital on that day She was suffering from an enormous abdominal tumour She had noticed a gradual enlargement of the abdomen for eighteen months it commenced on the left side she had had swelling of the legs and feet for twelve months and difficulty in micturition for six months Dr Rowlands was not consulted until Christmas 1923 when he diagnosed ovarian cyst and advised operation but this the patient refused As the swelling was incapacitating her more and more and as she had several attacks of mild abdominal pain and pressure symptoms such as dyspnoea palpitation and flatulence she at last consented

She was tall emaciated and pale but free from jaundice She complained of pain in the epigastrium radiating to the upper part of the spine and flatulence after food but had not had biliary colic She had lost flesh and strength especially during the last six months The pulse was 85 the temperature and urine normal The abdomen appeared to be completely filled by a large ovarian swelling projecting in front but no bulging in the flanks It was immovable dull to percussion and a distinct fluid thrill could be elicited A diagnosis of cystic ovarian tumour was made

Operation

This was performed on April 23rd under ether anaesthesia The abdomen was opened by a right paramedian incision extending from the level of the ensiform cartilage to just above the pubes The abdominal cavity contained an enormous multilocular cyst arising from the left ovary Extensive adhesions to the parietal peritoneum were separated and the tumour easily delivered through the wound and removed by dividing its pedicle distally between clamps The pedicle which was four inches broad was transfixed and ligatured and the raw area covered in by Lembert sutures

Nothing abnormal was found in the pelvis and the stomach duodenum and liver were normal but several calculi could be felt in the gall bladder It was removed in the usual manner the cystic duct and artery being ligatured separately bleeding from the raw surface of the liver was controlled by deep catgut sutures A moderate sized drainage tube was inserted to the stump of the cystic duct and the abdominal wound closed in layers

Apart from transient retention of urine and distension of the abdomen the patient made a splendid recovery the drainage tube was removed on the sixth day and the discharge gradually ceased She left the hospital in three weeks free from symptoms and with the wound soundly healed In the middle of September she was about her household duties and feeling very fit

The Tumour—The tumour which measured 50 inches in circumference and weighed 46 lb was multilocular but fully five-sixth of it was formed by a big cyst which occupied its anterior part it contained thin yellowish fluid the remainder of the tumour was composed of six smaller loculi which contained mucous material

The gall bladder was lightly enlarged its wall was thickened and fibrotic It contained clear mucus and two large spherical gall stones and numerous dark brown faceted smaller stones

J F Thomas, M D,
Senior Surgeon Carnarvonshire and Anglesey Infirmary Bangor

ACUTE INTUSSUSCEPTION

While I was house-surgeon to the Beckett Hospital Barnsley Yorkshire a healthy looking male child aged 5 months was admitted with a history of diarrhoea of two days' duration and the passing of blood and mucus in the stools The bowel was found to be prolapsed for about four inches through the anus A large sausage-shaped mass could be palpated on the right side of the abdomen The prolapsed bowel was easily reduced inside the rectum, but when pressure was removed it again came down, this time to a distance of about six inches owing to the continual straining of the patient

Under general anaesthesia the abdomen was opened by an incision slightly to the right of the middle line, and the rectus muscle displaced outwards The diagnosis of intussusception was verified, and my assistant having reduced the bowel through the anus, pushed the apex of the intussusception up within reach of my hand inside the abdomen Reduction was easily accomplished by pressure some slight difficulty being experienced in the last portion owing to the oedema present The intussusception was of the ileo-caecal variety and the usual enlarged lymphatic gland was present at the ileo-caecal junction

Recovery was uneventful, and the child was discharged at the end of the third week

I have to thank Dr Edwin Orsmond for his skilled assistance during the operation

Indian Station Hospital Poona India

Reports of Societies.

THE EVOLUTION OF NEUROLOGY AND ITS BEARING ON MEDICAL EDUCATION

Dr. F. Farquhar Buzzard, the new President of the Section of Neurology of the Royal Society of Medicine, delivered his address from the chair on October 9th, and took for his subject "The evolution of neurology and its bearing on medical education."

Neurology (said Dr. Buzzard) was the oldest of the medical "ologies," not perhaps by right of primogeniture, but because of its exceptional precocity. This precocity arose from the fact that even in infancy its anatomical elements were more readily cemented together by physiology than was the case with any other branch of medicine. In the result the problems of neurology had become progressively more straightforward and perhaps easier of solution than those of other departments of medicine. The science of neurology was approaching exactitude in regard to the relationship of symptoms and physical signs to disorders of function and changes of structure. During the last quarter of the nineteenth century the edifice of neurology was in process of construction. The foundations were chiefly composed of anatomical facts interspersed with meagre physiological details by way of "mortar." The superstructure grew in height as disease after disease was quarried and laid in place, but in the absence of any considered plan the architecture was faulty and lacking in proportion and design. Nevertheless, incomplete though it was, it was an edifice to be proud of, and every year saw the foundations widened by additions to the knowledge of anatomy and physiology.

In speaking of present and past conceptions of morbid processes, the speaker employed a sporting analogy. He likened the earlier conceptions to the golf ball which was stationary before the player: the physician might miss it, the surgeon might slice it, only a quack might drive it out of bounds or into a hazard without penalty. The later conceptions were like the cricket ball which came from a distance and was deceptive in its flight, and the swerve of which required watching. A long experience of the bowler's wiles might enable the batsman to play the ball with increasing confidence, but the danger of being bowled, stumped, or caught out could never be very far away. "We want more cricketers and fewer golfers in our ranks."

In its early days (Dr. Buzzard continued) a specialized offshoot like neurology was apt to be isolated from its fellows. Only as it neared maturity was its relationship to the main trunk and the other branches clearly determined. It was not his intention to depreciate the work which had been done in the past, but the time had come when the map of medicine required careful reconsideration from the point of view of the medical student. It had become a maze rather than a map—a maze from which innumerable superfluous names and countless blind alleys must be eliminated in order that the main roads might stand out clearly for the student of medicine to see and follow. As an examiner he had been appalled at the amount of material the candidate was expected to assimilate. The medical curriculum required revision. In his own time he was taught physiology and anatomy, passed an examination in those subjects, forgot practically all he had learned, and started on new subjects called medicine and surgery. Three years' work, during which he learned much about disease and little about health, enabled him to pass another examination and qualify. A year later his steps were turned to Queen Square, and his thoughts to neurology, and he found that he had to go back to the beginning of things, relearn the anatomy and physiology of the nervous system, and so gain what was to him an entirely new conception of the relationship between health and disease. As time passed he realized that this conception was applicable not only to neurology but to other branches of medicine. Did the student of the present day go through a different series of experiences? He thought not. After two or three years of study of anatomy and physiology he had no knowledge of the normal standards as applied to the living human being, and therefore had not the necessary data to enable him to detect variations from the normal. Yet in the next two or three years he had so much to fill up his time that there was little or no opportunity of making good this deficiency, with the result that he qualified with such acquaintance with minute details as was required of him, but more or less ignorant of health and uncertain in his detection of disorders of function.

A newly qualified practitioner should be familiar with health as represented by normal structure and function, he should have at his fingers' ends all the ordinary tests employed in medicine for detecting variations from normal function, he should be thoroughly acquainted with morbid processes, whether of degenerative, vascular, inflammatory, or neoplastic origin, and capable of recognizing the alterations of structure which they produced, he must be intimate with the history of disease as illustrated by its clinical course, and he should be well grounded in the established principles of treatment, realizing that therapeutic measures were very unstable and depended largely on the vogue of the moment. Under the present system very few such qualified men were adequately equipped for the practice of medicine, though fortunately only a minority assumed really responsible positions without passing through some further kind of apprenticeship. In his view the student who had passed the threshold of anatomy and physiology should be made to feel that he had entered medicine. He should be faced with living as well as dead subjects, and his task should be made easier by facilities for comparing the normal with the abnormal. The study of musculature should embrace not only the original insertion of muscles, but their living function, their daily and hourly use, and the methods by which their action or inaction could be demonstrated. And what applied to the musculature applied to other tissues and organs. He outlined a reformed curriculum which would bring about what he had in view—the expansion of anatomy and physiology, the adoption early in the medical curriculum of methods, such as radiology, by which structure and function could be viewed from additional standpoints, and the study of psychology, which should also begin during the physiological era of the curriculum. His proposed alterations in teaching would necessitate some change in the point of view of examiners. Those conducting final examinations would need to satisfy themselves that candidates were adequately educated rather than made replete with fact, and that their knowledge of medicine and surgery was built on foundations of physiology and anatomy sufficiently strong to support the additions which post-graduate study would add to it year by year.

Dr. Henry Head, in proposing a vote of thanks, said that from the beginning physiology as taught at Queen Square had always associated structure and function. He recalled vividly his own early experiences at Queen Square where he had to revise many things he had previously learned. One of his first interviews was with Rivers, who asked him what case he had been doing that day. "Just a straightforward hysteria," was his reply. "Then," said Rivers, "I am sure it is not." That sent him (the speaker) back in a humble mood, and he need scarcely say that the case proved to be one of disseminated sclerosis. Many such shocks were necessary, however, before he was sufficiently humbled to look at the work in the wards from the old point of view of the physiological laboratory. What he had been brought up to look for in his previous hospital experience was structure, now he was face to face with function. From the very first day at Queen Square structure and function had been associated, and it was because of this that neurology had made its advances. He was delighted to hear Dr. Buzzard insist that those great principles which underlay the progress of neurology were applicable to the practice of medicine, and that neurologists had been ahead of the rest of medicine, not because they had more knowledge than other people, but only because they had a better method. It was this better method that should be taught to the younger generation, and he welcomed Dr. Buzzard's proposed revision of the curriculum.

TINTED LENSES AND THEIR USES

At the meeting of the Ophthalmological Section of the Royal Society of Medicine on October 10th, Sir ARNOLD LAWSON, the incoming President, delivered his address from the chair.

Sir Arnold Lawson took for his subject 'Tinted lenses and their uses." A good deal had been written, he said, about the ultra violet rays and their destructive effects on the eye. The general public had become imbued with a haunting fear of daylight, so that the wearing of glasses which eliminated ultra violet rays had become a fashion. Tinted glasses seemed to be prescribed in an indiscriminate and indefinite way with the idea of getting rid of the ultra-violet bugbear. But what was the real truth about the human eye and its susceptibility to ultra violet rays? A great deal of protection was afforded by the cornea and the crystalline lens, especially the latter, against ultra violet excess. Only ultra violet of a very narrow and harmless range of wave-length—a small proportion of the possible ultra-violet radiation—reached the retina under normal conditions. Ordinary sunlight in the lower altitudes was rather poor in ultra-violet the eye was constructed to allow the ultra violet rays of ordinary sunlight to pass harmlessly to the retina, and a certain excess was excluded by the protective properties of the eye itself. There was no need, therefore, in the normal person to protect the eyes from ordinary daylight, and what he had been saying about the ultra violet applied equally to the infra red. Certain factors came in, however, to complicate the situation in some cases. In the Alps, for example, there was increased intensity of daylight, owing to the rarefaction of the atmosphere and the absence of vapour. The spectrum was extended at both ends though more markedly at the red end than at the violet. Again in certain states of health prolonged exposure to quite a moderate degree of light might be harmful because of the lowering of functional power. The presence of glare—that is an undue amount of reflection from lower surfaces—was another factor which might lead to trouble. Here again however, it was the luminous and infra-red portions of the spectrum rather than the ultra-violet which were involved. Snow-blindness was not due so much to excess of exposure to ultra violet radiation as to excess of exposure to infra-red. Finally various occupations required special adjustments. Acetylene welding for instance exposed the worker to an intense ultra violet radiation glass-working to heat radiation.

He proceeded to show the results of certain tests of the spectroscopic value of tinted glasses. Incidentally the thickness of the glass was an important factor. Peacock blue of 2 mm. thickness shut off the red orange and part of the green, and also interfered with the blue and violet and eliminated the ultra-violet but similar glass 0·5 mm. in thickness let through a great deal more both of the red and of the violet. The absorption factor in the case of thin glass was enormously lessened, to a much greater extent than he would have thought possible if he had not seen the spectroscopic records, and he hoped that the Section or the Council of British Ophthalmologists would take steps to bring about some uniformity in the thickness of the glass used for tints. Taking glass of 2 mm. thickness the result of his investigations was to show that the old London smoked glass from the point of view of protection against ultra-violet radiation, was almost as good as the deeper shades of Crookes glass, and that as regards the red end of the spectrum it was better than the Crookes. If it was desired to eliminate both ends of the spectrum peacock blue should be used. The violet end of the spectrum was absorbed best by fieuzal glass. Crookes 1 and 12 were not really tinted glasses at all but they furnished a useful way of protecting a sensitive eye in mild glare, and they did not disfigure the face or alter the colour values. For patient with healthy eyes but who were physically or mentally abnormal Crookes glass especially B and B2, was excellent but he thought that too much protection should be discouraged, and that as the patient improved in health the wearing continuously of some kind of tint should be gradually abandoned, because it was likely to become a pernicious habit. Cataract due to glass blowing was caused by infra red rays, and tints such as fieuzal 4 or 5 or peacock blue afforded the best prophylactic. Nothing was more harmful in the early stages of cataract than exposure to bright light of any kind. In cases in which a habitual tint was wanted there was nothing more comfortable than Crookes glass but in active inflammatory diseases of the retina and choroid he would much prefer peacock blue.

In the course of a brief discussion, Mr. H. B. GRIMSDALE indicated a possible use for tinted glass in cases of middle-aged persons who were reluctant to give up their participation in sport and yet found difficulty in focussing moving objects. This difficulty, he believed was due to a difference between the luminous perception of the two eyes and the use of a tinted glass reduced the perception of the normal eye more to the level of the other so that the sight of the two eyes became better co-ordinated. Persons who had used these glasses had regained their efficiency as a game.

Mr. ERNEST CLARKE said that the fear of glare came in with the advent of carbon points in early electric light, and the fear was now disappearing. He had found Crookes 1 and 12 of enormous benefit to people bordering on neurasthenia who were hypersensitive. The great point about the Crookes glass was that it did not cut off the luminosity, and was not unsightly. The late Sir William Crookes had told him that it would be too expensive commercially to separate from the serum the metal didymium, which was an adulteration. (A subsequent speaker stated that the value of the Crookes glass was in the didymium, one of the rare earths which had a positive absorption of the spectrum.)

Mr. TEACHER COLLINS said that he had advised amber-tinted glasses considerably. He was first led to appreciate their value by the experience of a medical colleague who was a mountaineer, and who on the morning of a climb, painted his face yellow a procedure which caused amusement to the other members of the party but at the end of the day he was the only one who face was not burning red. The speaker believed that snow-blindness was really due to the effect of ultra violet rays on the surface of the eye and accordingly he had ordered amber tinted glasses. A surgeon on an Antarctic expedition had assured him that all the party wore amber-tinted glasses to protect themselves from snow-blindness and even the ponies were similarly protected. Workers in the neighbourhood of furnaces, and cooks in the neighbourhood of ovens, found great relief from the wearing of peacock blue.

The experience of another speaker was that in mountaineering green glass was more comfortable than peacock blue and gave the climber a better appreciation of objects, while yet another said that smoky amber glass had proved a perfect success in the case of a party on a shooting expedition to Labrador.

FLOURS AND CHILD NUTRITION

At a meeting of the Medical Officers of Schools Association on October 8th, Dr. L. R. LEIPHEIPER presiding a discussion took place on the relative values of stone-milled and other flours and breads in relation to the nutrition of the growing child.

Dr. ROBERT HUTCHISON said that the subject of the relative merits of roller-milled and stone ground flour as a food for growing children had given rise to a great deal of controversy, and was one on which very divergent opinions were held. As a basis for discussion it would be well to recall a few chemical facts about flour. The wheat berry consisted of three parts (1) the germ or embryo, (2) the husk or bran (3) the endosperm. Of these the last made up by far the largest part of the berry. Each of these parts had its own characteristic chemical components. The germ consisted largely of soluble proteins the exact nature of which was to some extent unknown and was rich also in phosphorus and fat. The bran contained a relatively large amount of mineral matter along with a considerable amount of protein derived from its inner layers. The endosperm consisted mainly of starch, but also contained some valuable proteins such as gluten. Water soluble vitamin was contained in the germ and bran, but was absent from the endosperm. In roller milling a white flour was obtained which

represented about 70 per cent of the whole wheat, and was derived entirely from the endosperm In stone-ground flour about 80 per cent of the whole wheat was yielded, and a considerable part of the germ and some of the inner layer of the bran was contained in the flour It followed, therefore, that stone-ground flour would be richer than white flour in proteins, in phosphorus, and in vitamins It was true that the difference in protein was not very great, for it had been calculated that even if the whole of the germ was included in the flour the protein content of the latter was increased only by about 0 6 per cent This, however, was not quite the way to look at the matter, for it was the quality of the protein that was of importance, and not mere quantity, and it had been found that the proteins of the germ were peculiarly suited for the promotion of growth —in other words, they were of specially high biological value Little was known as to the form in which phosphorus was contained in stone-ground flour There was no reason to doubt, however, that it was in a form available for nutrition and capable of combining with calcium in bone formation The question of vitamins he might pass over, as it would be dealt with by others There remained to be considered the digestibility of stone-ground flour and the "availability" of its nutrients As to this it might be said with confidence that it was as completely digestible (in the physiological sense) as white flour Indeed, experiments made during the war showed that even wholemeal flour was much more completely digested than was at one time supposed, provided it was finely ground Nor was bread made from stone-ground flour, if properly baked, less digestible (in the popular sense) than white bread, while it had the advantage of being more "staying" to the stomach

Dr Hutchison then turned to consider the bearing which these chemical and physiological facts about the two sorts of flour and the breads made from them had upon the question of the choice of bread for the feeding of growing children It was generally agreed that during growth there was required (1) an abundant supply of energy (calories) in the diet, (2) a relatively large proportion of protein, (3) a sufficiency of mineral matter, especially phosphorus and lime, and (4) a supply of accessory constituents or vitamins How, then, were the two forms of bread calculated to meet these requirements? With regard to the supply of energy there was nothing much to choose between them, but with regard to protein it was obvious that the advantage was with the stone-ground flour It was true that the difference in total protein was not very great, but, as he had already said, some of the protein derived from the germ was of specially high tissue-building value In the case of children who had an abundant mixed diet this special protein was obtained from other sources, but where the diet was mainly composed of bread the difference might become of considerable importance The same was true of the mineral constituents In the case of a child fed on an abundant and mixed diet the comparative poverty of white flour in this respect did not matter, but if the child was fed mainly on bread it might make all the difference to growth and bone formation

There remained the important question of the vitamins, into which he would not enter in detail But it was evident that the opinion one formed as to the relative merits of white and stone-ground flour would depend largely upon the importance to be attached to the vitamins in nutrition His own view was that there was a tendency at present to exaggerate the importance of the vitamins He agreed that they were necessary for healthy growth, and that absence of the water-soluble vitamins caused beri-beri and scurvy These diseases, however, were never met with in this country, and he was not aware of any clear evidence that general ill health, apart from these specific diseases, was due to vitamin defect He could not help feeling that if the diet was right in other respects, the vitamins would look after themselves, and that in such an abundant and mixed diet—which was what they should aim at—the question of what sort of flour the bread in the diet was made from was of minor importance

Dr C E Shelly dealt in some detail with the manner in which the grain of wheat was treated in the production of flour by the stone-grinding mill The result of the process was that wholemeal flour contained everything that was in the grain—both layers of bran, the endosperm (starch), a small amount of gluten, cellulose, and the germ with its valuable contents The bran and the germ between them gave it a slightly dark colour, so that it did not make such an attractive looking bread or pastry The bran could not be looked upon as an essentially nourishing part of the grain, and it had an action which was not quite comfortable to the modern stomach An occasional change to wholemeal bread was useful, but as a constant article of diet it might be improved The bran could be removed from the wholemeal by a combination of winnowing and sifting, but in depriving the flour of the bran it was deprived of a very small percentage of the germ as well There remained a form of flour which was conveniently named millstone flour This could be sifted again to greater fineness and whiteness, though with each sifting a little more of the germ was lost This millstone flour was a complete food, it cost a little more than white roller milled flour, but it was cheaper in the end because it went further It made a kind of bread which invited mastication It was said not to keep so well as ordinary flour, but with this he did not agree, it only needed to be kept under proper conditions In the case of roller milling the grain was squashed rather than ground, and the germ was cut away from the rest of the grain The result of the roller-milling process was to deprive the flour of the germ and the bran, leaving the endosperm, which was largely starch, a small amount of gluten, and some cellulose The germ and the bran were sold under the misleading name of "offal," and the flour, representing mainly the endosperm, was sold as a starchy kind of food Was it fair that children should be made to take a bread which had been deprived of some of the best qualities of the original wheat and which did not contain the nourishment to which they were entitled?

Sir Harry Baldwin said that the jaws of civilized people in quite modern times had become deformed or ill developed, to their great detriment, to say nothing of the quality of the teeth It seemed to him that this deformity had arisen during the period over which we had been reducing our vitamins by removing them from the flour There was a good deal to suggest that the small and misshapen jaw was due to partial avitaminosis in early life This deformity conduced largely to dental caries The general opinion of dental surgeons was that caries was mostly due to the kind of food eaten, especially the sticky carbohydrate food which accumulated in the interstices between the teeth The bread from finely ground white flour produced a sticky substance which remained about the teeth most tenaciously The staple food of the poor should not be deprived of its important natural constituents simply to pander to the vitiated taste for white flour

Dr G E Friend, medical officer to Christ's Hospital said that at Horsham the boys had been fed on a bread made from stone-milled flour containing a varying proportion (from 76 to 80 per cent) of the whole grain During the last two years a certain amount of the bread had been made from a flour containing 86 per cent of the whole grain It was found that the boys at first would not eat very largely or for any considerable period of the stronger bread, but during the winter months nearly one third of the bread was of the 96 per cent kind As a result of the use of these breads there had been a great improvement in the teeth When the school first removed to Horsham the average number of carious permanent teeth per boy found at each annual inspection was four, now it was 1 5 He could not claim, of course, that the improvement was entirely due to the use of wholemeal bread In other respects the boys had improved, particularly in weight, though here again other factors came in as well as food The chief value of the wholemeal flour, in his opinion, was that it ensured proper mastication

Dr Ogier Ward gave the percentages of waste which took place at the successive crushings in the process of roller milling He added that since he had been able to induce his local baker to produce mill tone bread he was content with nothing else Mr Guldensi (St Guy's Hospital) gave an account of some experiments which

during the war which went to prove the value of wholemeal bread Miss May Yates said that it was quite possible to make wholemeal in roller mills, with some adjustment of the machinery, and this statement was endorsed by another speaker who was a baker and who gave some technical details of the process

The following resolution, proposed by the Chairman, Dr Lempriere, was carried without dissent

> That whiteness of flour is not in itself necessarily an indicator of its value as a food but that the natural germ containing bread made from an 80 per cent flour tastes better and is more nutritious particularly for the growing child and should be provided

It was stated that this would be sent to schoolmasters and educational authorities

Reviews.

SOME MEDICAL ESSAYS

Dr Arthur F Hurst's *Essays and Addresses on Digestive and Nervous Diseases and on Addison's Anaemia and Asthma*[1] will be heartily welcomed by the numerous readers of these papers, which originally appeared in this and various other journals not only because they are now available in a convenient form, thus providing a continuity not otherwise so easily attainable, but because they have been revised and expanded so as to represent the author's latest opinions Thus the account of achalasia of the cardiac orifice of the stomach, which appeared in the *Quarterly Journal of Medicine* in 1914, now contains a reference to a paper written in 1922, and is supplemented by an article on pelvi rectal and anal achalasia or so-called congenital idiopathic dilatation of the colon The address appropriately delivered at Harrogate on 'The sins and sorrow of the colon," recalling a somewhat similar title for a lecture on splenic ailments by his late senior colleague, Sir I Taylor is a happy blending of the historically interesting with the practical applications of recent research The chapter on ulcerative colitis which appeared in the *Guy's Hospital Report* (1921), of which he is the successful editor, has an addition, dated last year showing that ten cases have now been successfully treated by intravenous injections of antidysenteric serum, a control trial of simple horse serum failing to give the same benefit

The two lectures on gastric diatheses—the hypersthenic which disposes to duodenal ulcer, and the achlorhydric with its association with appendicitis, cholecystitis pancreatitis, and rheumatoid arthritis—are followed by a complete statement of his present views on "Addison's [so-called pernicious] anaemia" and its relation to subacute combined degeneration of the spinal cord In 16 cases of this nervous disease Dr Hurst has found complete achylia gastrica which is such a constant factor in pernicious anaemia he argues that in both these diseases the loss of the antiseptic action of the normal gastric juice makes it possible for bacteria such as the *Streptococcus longus* swallowed in cases of oral sepsis, to infect the intestines and produce haemolytic and neurotoxic bodies, and that the relative amount of these two toxins determines whether the haemolytic or nervous symptoms predominate The nervous disorders of the stomach and intestines, the hysterical element in organic disease, and contractures are considered in a clear and illuminating style and there are interesting accounts of asthma, appendicular dyspepsia, and cholecystitis and gall stones in the light of recent research Throughout the work the value of team work, which is generously acknowledged, is obvious and the reader cannot but be impressed by the new and attractive aspects of the application of research to medical practice, set forth with an open mind as to future modifications that further investigations may make necessary

"THE EXTRA PHARMACOPOEIA"

All persons interested in the progress of therapeutics will welcome the appearance of a new edition, the eighteenth, of Martindale and Westcott's well known *Extra Pharmacopoeia* It is four years since the last edition appeared, and the first volume only is now issued the second is to follow in due course The book has for so long been so popular with the medical profession as a handy work of reference that it is superfluous to describe its general scope In spite of the continuous and rapid advance of therapeutics, the authors still aim to give an account of the materia medica chemistry and therapeutic action of every drug the medicinal use of which is in any way established

The two outstanding impressions created by a survey of the present volume are—first, that therapeutics have made very extensive and remarkable advance in the past four years, and, secondly, that the authors have shown indefatigable energy in condensing into their new volume a full summary of these advances

The following are some of the chief new features included in the present edition Insulin is the most important new therapeutic substance described, eight pages are devoted to a description of the discovery, modes of preparation, standardization and therapeutic employment of insulin A number of important new trypanocidal and spirochaeticidal remedies are described the chief of which is the synthetic substance 'Bayer 205", it is well treated in a page and a half A note is also given concerning No 309, the French product prepared by Tournemu this year, which is probably identical with 'Bayer 205" Trypanamide, the new American product, is also described

No fewer than six pages are devoted to the various bismuth preparations that have been introduced for intramuscular injection in the treatment of syphilis The two new mercurial compounds flumerin and mercurochrome, are mentioned shortly The former is a compound for use in syphilis and the latter is a very valuable disinfectant suitable for application to mucous membranes Some interesting new compounds introduced by Dr Martindale also deserve special mention—namely aspriodine, a compound of iodine and salicylic acid sedasprin, a compound of bromine and salicylic acid and emetine periodide, which is stated to be superior to emetine bismuth iodide in the treatment of chronic cases of amoebic dysentery Besides these new compounds the advances in therapeutic knowledge during the last few years have necessitated the rewriting of the accounts of the pharmacological actions of many other drugs The ten pages devoted to the description of the vitamins contain material that is nearly all new work, and the same is true of the article on protein therapy

These notes on a few of the salient new features of the present edition show very clearly how careful the authors have been to bring their book completely up to date Great praise is due to them for the care they have taken to give a full account of all the recent advances in therapeutics, but they have performed another almost equally valuable service by wielding the blue pencil in a drastic manner for they have cut out a large number of useless drugs and thus have prevented any appreciable increase in the size of their book A special feature of the new edition which practitioners will find of the greatest value is an account of the provisions of the Dangerous Drugs Acts A study of this article will save medical men from incurring the fearsome penalties enacted in these Acts The authors provide an interesting preface to the volume in which they mention the chief new features, and also discuss a number of interesting problems They criticize the Dangerous Drugs Acts severely, for, as they point out The Acts in fact punish those who ought to be supplied for the sins of those who abuse the drugs" The preface concludes with an appeal to practitioners to support home industries by doing all in their power to increase the use of British drugs

In conclusion we may say that the present volume keeps up the high standard set by the previous editions of this

The Extra Pharmacopoeia of Martindale and Westcott By W H Martindale Ph D F C S and W Westcott M B Lond D P H Vol I Eighteenth edition London H K Lewis and Co Ltd 1924 (Foap 8vo pp xxxviii + 1163 2nd ed. net)

work, and that practitioners will find this edition just as complete, up to date, and useful a work of reference as they have found its predecessors to be

THE MAYO CLINIC AND FOUNDATION

THE remarkable activities radiating from the Mayo brothers almost take the reader's breath away, for the fifteenth volume of the *Collected Papers of the Mayo Clinic and the Mayo Foundation*[1] contains references to 308 papers written by 148 authors working at one or other of these institutions, which have appeared during 1923 The present year sees a change in the policy of publication, last year the two volumes published contained 2,100 pages, this year a single volume of less than 1,400 pages has been brought out, but 97 of the 308 papers are given by title only and others are abridged or abstracted This plan has been adopted for papers dealing with subjects of technique or of such a specialist character as to be of limited interest to the general surgeon or physician The papers, which have been published elsewhere, are grouped under the headings of the alimentary tract, the urogenital organs, ductless glands, blood and circulatory organs, skin and syphilis, head, trunk and extremities, brain, spinal cord and nerves, technique, and general or miscellaneous As would naturally be anticipated, the largest number of papers deal with the alimentary system, they number 70, and 18 are given by title only, the urogenital organs are discussed in 41 papers, the head, trunk and extremities in 46, the ductless glands in 33, and the blood and circulation in 30 The last or miscellaneous group contains 41 papers, 18 of which are recorded only by title, but a few of these may be mentioned on account of their interest, in recording his observations on medical conditions in Europe, Dr Charles Mayo says that the surgeons are doing more widely diversified work than the average surgeons in America, fewer fields of surgery being held by specialists Dr William Mayo, who contributes six papers, devotes much attention, in his address to the American Surgical Association on "A Question of Size," to the atom and the molecule, and pleads that the overburdened students of medicine should be taught more biophysics, and that the time spent on chemistry should be correspondingly curtailed In his discussion of the distinctive features of undergraduate and graduate medical schools, Dr L B Wilson agrees that these two functions, which he describes as the preparation of general practitioners and the training of specialists, should remain distinct, but he believes that they should be closely correlated, and that a university should undertake them both Dr William C MacCarty in a paper on "The Pathologist of the Twentieth Century" deals with the real status of the pathologist in the profession, and urges a broad outlook and a closer approach to the patient Among his five other contributions to this volume is a combined discussion of the radiological diagnosis of gall-bladder disease, in which he states that among five thousand gall bladders examined microscopically seventeen only were normal This volume, like its predecessors, is a veritable storehouse of information and a monument to the Mayo brothers

THE MICROSCOPIC AND GENERAL ANATOMY OF TEETH

THE second edition of Mr HOWARD MUMMERY'S *Microscopic Anatomy of the Teeth*[2] has been enlarged by some 200 pages by the addition of a second part on the general anatomy of the teeth, both human and comparative Throughout the book we are conscious of the philosopher trying so to unravel the tangled skein of his special knowledge as to co-ordinate his facts with the great central idea of evolution The dominant note is evolution, and this, perhaps, explains the use of the hackneyed word "comparative" in the title to designate an account of the teeth of all creatures, extinct or living, of lesser degree than man

But it is the title only we would have altered The idea itself gives life, and a most fascinating life, to the dry bones of odontology The evolution of the human molar provides matter for a most interesting chapter "Concrescence" and "tuberculy" are displaced and the "dimer theory" takes their place, its claims resting largely on the histological work of Bolk on the developing teeth of existing animals A wider investigation into the enamel organ of the various orders of living things shows that some enamel organs resemble secreting glands, some the like the human enamel organ characterized by huge ameloblast cells, while in others the first formed and actually active ameloblasts are replaced at a later stage of enamel formation in the same tooth germ by a secreting gland The question arises, Which is the primitive method of enamel formation, and can the enamel organ be used as a help in tracing the relationships of animal life? The enamel of some animals is shown to have a definite fibrillar basis, and we would ask the author, Does this point to a closer relation between enamel, dentine, and bone than has hitherto been allowed?

The vexed question of the innervation of dentine is dealt with in the chapter on the dental pulp, and though we think that the author's figures show there is something in the dentinal tubules which needs attention, and may well be nerve fibrils, we cannot follow him in his description of a synapsis and nerve-end cells beyond from which the fibrils originate We cannot see in Fig 136 the neurofibrils in the dentine it is intended to show As a point in evolution we may wonder why an organ whose life is spent in calcifying itself till often no pulp remains should be provided with a nerve end organ worthy almost of a retina

The second part of the book has been rendered additionally attractive by illustrative plates, many drawn by the author himself, of the animal under discussion, or of its skull and teeth, taken from actual specimens In this connexion we may note the plate on the ancestry of the horse as especially illuminating We have a few complaints to make The paragraphing of the letterpress is sometimes faulty; the historical review of the literature on dentine immunity tion ends curiously in a description of persistent pulps and injured elephant tusks Can the author find no word but "anlage" to express his meaning on page 428, or if he must use it, can he explain just what the original German author had in mind? As it stands it is simply mystery

The author hopes the book "will meet the requirements of the B D S degree of London and the various other university degrees and diplomas" Beyond a doubt it will, and if any man of mind and leisure take up this volume he will find it hard to lay it down, and will run great risk of becoming an ardent worker in the fascinating field of odontology

THE ACTION OF ALCOHOL ON THE HUMAN ORGANISM

SOME years ago (1918, vol i, p 238) we drew attention to the work issued by the Advisory Committee appointed by the Central Control Board, under the title of *Alcohol: its Action on the Human Organism*, which was intended to afford a basis for future research and as a review of the existing state of scientific knowledge as to the action of alcohol on the human organism The second edition of this valuable and admirably impartial report,[3] which has been edited by the Alcohol Investigation Committee of the Medical Research Council, contains numerous additions such as an account of the conditions affecting the rate of absorption of alcohol, as shown by the work of Mellanby and Miles the experiments carried out by Vernon, McDougall and Smith, and Miles for testing the effect of alcohol on the accurate co-ordination of nervous and muscular activity which is necessary for skilled movements, statistics illustrating the relations of alcoholism and insanity, and recent work on the effect of parental alcoholism on the offspring

[1] *Collected Papers of the Mayo Clinic and the Mayo Foundation* Edited by Mrs M H Mellish Vol xv, 1923 Philadelphia and London W B Saunders and Co 1924 (Med 8vo pp xviii + 1377 410 figures 43 3s net)

[2] *The Microscopic and General Anatomy of the Teeth, Human and Comparative* By J Howard Mummery, C B E, F R C S, D Sc Pern L D S Eng London Medical Publications Second edition Humphrey Milford Oxford University Press (Demy 8vo, pp iv + 618 42 plates, 270 figures 35s net)

[3] *Alcohol: its Action on the Human Organism* Abridged and revised London Published by His Majesty's Stationery Office 1924 (Cr 8vo, pp xx + 170 1s 6d net)

A new chapter has been added on alcohol as a drug, in which the conclusion reached is that its main value is due to its narcotic action It is also recognized that alcohol possesses a limited food value under conditions in which ordinary nourishment cannot be taken, and that by diverting blood from the internal organs to the surface it helps to ward off a chill On the other hand, it is shown that there are no grounds for the popular belief, still held by some medical practitioners also, that alcohol possesses a stimulant action on the heart, respiration, and vital activities in general, or that it has a protective value against infection The chapter on alcoholism and longevity contains a criticism of Professor Raymond Pearl's work, and a new paragraph relating to the risks of venereal disease and accidents in non-abstainers The appendices dealing with the total consumption of beer, spirits, and wine in the United Kingdom and the annual deaths from alcoholism and cirrhosis of the liver have been brought up to date

AN INTRODUCTION TO PHYSICAL ANTHROPOLOGY

Under the title of *A Short Course on Physical Anthropology*,[1] Professor Drennan has published a serviceable little book which provides a most helpful introduction to this subject Although primarily written for the students of anatomy of the University of Capetown, it will probably be used more widely, since it serves as an introduction to the larger textbooks and is likely to stimulate greater interest in anthropology among medical students The subject is dealt with in an elementary manner throughout and the simpler methods used in craniology are described in a clear and practical style In the later pages brief reference is made to some of the most significant discoveries of fossil man The reader is thus prepared for the study of monographs in which full accounts of primitive human remains may be found A list of the more important books of reference is included in the preface Professor Drennan is to be complimented upon producing a very modest book, likely to be welcomed and appreciated by teachers and students of anthropology

MEDICAL HISTORY OF THE WAR

A correspondent writes to the effect that he does not think the medical authorities in Egypt did in fact expose themselves to the unfavourable comment of the critics mentioned in our review (British Medical Journal, July 19th p 106) of the third volume of the *Medical History of the War* (1) The officers successively in charge of the splint factory at Alexandria were also in charge of the surgical division of one of the hospitals (2) They got no extra pay for their extra work and as far as he knows such work was not recognized by the award of any decoration (3) The factory was kept open in 1919 for the purpose of preparing sets of models of all appliances used in the East by the medical services, including ambulance sand carts and sledges, to meet the wishes of various departments One set was presented to the Khedive, who took much interest in the enterprise

This letter has been shown to our reviewer, who says that he has now had an opportunity of reading the final annual report on the work of the Central Splint Factory at Alexandria which is in question In this the officer, the last and longest in charge of it, gives a history of the undertaking from the beginning The three officers successively in charge were also in charge of the surgical division of No 21 General Hospital Starting as merely an annexe to the splint room of this hospital, the undertaking rapidly grew to be very large, its wages bill alone eventually reaching £2 000 a year The calls upon it, many of which came from far distant commands, were so great that work had often to be carried on until nine at night throughout the whole week Similar factories, our correspondent holds will always be necessary in great overseas wars, and it is an advantage that they should be managed by a surgeon Those in charge at Alexandria found themselves handicapped in some degree by lack of technical knowledge, and of experience in managing workmen, and in keeping accounts on a large scale Hence any future appointees should be secured opportunities of studying the subject The factories should be mainly assembly shops, the splint parts being cut by machinery and supplied by contractors This was in effect the plan eventually adopted at Alexandria The work of the officers in charge was gravely increased by the multiplicity of small variations of pattern demanded by medical officers and the confusing names given to them Young surgeons proved very fertile in devising apparatus, but provided very imperfect specifications and drawings Consequently the officer in charge, besides drawing up an elaborate nomenclature, had often to make new drawings, or even paper or other model of the splints demanded, before the workmen could understand what was required He suggests that in order to obviate such difficulties on a future occasion a committee should draw up a list of standard splints detailing the measurements necessary and the best materials to use for each The same committee should also emphasize the fact that apparatus, however well designed, can play only a minor part in good surgery

Commenting on this report, our reviewer observes that it shows what excellent work outside their own true province medical officers can do when willing to undertake any and every task demanded of them He thinks however, that the critics mentioned by him would probably not have been silenced by the double employ of the officers concerned They would have maintained that it is not economic to employ surgeons on work which can be done by less highly trained and more easily obtained officers, and that this is the case in connexion with splint supplies In France splints were standardized at an early date by an expert committee and it would have been considered the duty of officers in charge of surgical divisions to discountenance unnecessary demands for other than regulation patterns Had the work of a hospital in France been of such a kind as to allot of the surgical officer managing an important enterprise outside its purview in addition to the duties of his appointment the staff should have been reorganized so as to effect a corresponding economy in other medical personnel In France quartermasters were in charge of all store dealing with surgical apparatus and their repair With regard to our correspondent other remarks, the reviewer writes that extra pay is allowed in the P A M C, not for extra work but as an inducement to medical officers to qualify for appointments requiring special knowledge for their adequate fulfilment Decorations other than those for services in action would seem usually to have been awarded in relation to the prominence of the appointment held The continuance of the factory for the purpose indicated is one of the many expenditures to which the taxpayer would probably have objected as unnecessary had he been aware of them

NOTES ON BOOKS

The second volume, devoted to children's diseases, in the treatise of medical pathology and applied therapeutics, edited by Professor Emile Sergent and MM L Ribadeau Dumas and L Babonneix[2] consists of two parts In the first Professor Weill and other members of the Lyons Medical Faculty (MM Pehu Gardere, Bertoye, and Dufourt) discuss infections of the newborn and certain acute diseases such as dysentery malaria, acute articular rheumatism, influenza, typhoid and diphtheria as seen in children, Professor Nobécourt deals with congenital and acquired heart disease M Merklen contributes chapters on diseases of the liver, kidney, and genito urinary apparatus and MM Babonneix Voisin, and Tinel give an account of various diseases of the nervous system. Most of the second part is devoted to a description of practical orthopaedics by MM Lance and Lamy the other articles include a discussion of anaemias in childhood by M Pives and a chapter on the therapeutics and pathology of childhood by M Terrien Every article is essentially practical and lucid and the work should be read by those who wish to gain a clear idea of French teaching in pediatrics

PREPARATIONS AND APPLIANCES

Insulin Hydrochloride

WE have received an interesting new product from Messrs Burroughs, Wellcome and Co—namely, insulin hydrochloride, made up in the firm's tabloid form Each tabloid corresponds with an average dose of 10 clinical units, and when dissolved in 0 5 c cm of sterile distilled water makes an equal volume of standard insulin The makers state that the product has been prepared under conditions approved by the Medical Research Council, has been submitted to exhaustive clinical tests, and has been found in all respects equal to standard insulin Provided its keeping qualities are established, this new preparation is likely to be a great convenience to all who wish to administer insulin The tabloids are convenient to administer are readily portable, and may be dissolved within the syringe

A Power Burette with Self adjusting Fluid Level

DR J P S DUNN (Ministry of Pensions Hospital, Orpington) writes to call attention to a new burette devised by himself and Mr L G Blore, assistant in the chemical laboratory The diagram illustrates a self filling and self adjusting burette, and the mechanism is as follows The burette is filled by pump pressure, which is maintained until the fluid level has risen beyond the zero mark shown in the diagram Upon releasing the pump the current is reversed

the surplus fluid in the burette is returned to the cylinder C by the siphon action of the connecting U tube (the capillary extremity of the short arm of which is adjusted a millimetre or more—depending upon the radius of curvature of the fluid meniscus—above the zero mark), and the fluid level in the burette falls automatically to zero The inflow may be delicately controlled by pressure upon the rubber pump, should, however, this pressure be unduly sustained, any tendency to overflow of the burette is readily checked by release of the "exhaust" The "dead beat" effect of the latter further operates to quench the oscillations which otherwise would be induced in the capillary extremity of the connecting tube Messrs Baird and Tatlock, 11, Cross Street, Hatton Garden, E C, are the makers For permission to publish, acknowledgement is due to the Director General of Medical Services of the Ministry of Pensions

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER

(*Continued from page 683*)

AT the second meeting of the Royal Commission on Lunacy and Administration and Mental Disorder, on October 8th, under the chairmanship of the Right Hon H J MACMILLAN, K C, the examination of members of the Board of Control was continued

SIR FREDERICK WILLIS, chairman of the Board, described the procedure followed on the discharge of a private patient

The CHAIRMAN It appears that a patient must always be discharged if the person on whose application he was detained desires the discharge, provided only that the patient is not in a dangerous state or unfit to be at large, in the opinion of the medical officer in charge, subject, of course, to appeal to your Board The person on whose application the patient has been detained might have an interest in his continued detention Suppose a person of that interest in the patient wanted his discharge, what action would he take?

SIR F WILLIS He could come to the Board of Control, and it interested in the welfare of the patient, and the applicant, to Commissioners would proceed, independently of the applicant, to investigate the case We have had such cases fairly frequently and they are always inquired into unless the person making the application is obviously unreliable, or the case relates to a patient whom we ourselves have seen quite recently and know all about There is no statutory obligation on the Board to do this, but in the case of a Government department "may has the effect of "shall"

SIR DAVID DRUMMOND Suppose there is no independent party interested in the welfare of the patient, and the applicant for the original order makes no move, who is entrusted with the control tion of the case?

SIR F WILLIS Our domestic machinery would bring to notice anything deserving attention

The CHAIRMAN remarked on the curious provision that a patient who had escaped from detention and remained at large for fourteen days was free from restraint, the order lapsed SIR F WILLIS said that he saw no reason in this stipulation it was probably an inheritance from the old days of laxity administration

The differences between the procedure on discharge of a private and on discharge of a rate aided patient were discussed and the CHAIRMAN remarked that here, as in the procedure with regard to the order of detention, the explanation of the difference was probably that there was no pecuniary inducement on the part of any person to retain the rate aided patient in institution

Dr BOND said, in reply to a question from the chairman, that full facilities and access to the patient would be given for independent medical examination Cases had arisen, although rarely, in which there was a difference of opinion between the medical superintendent and the outside doctor In such cases one would be inclined to give greater weight to the view of the superintendent, who saw the patient constantly, than to the outside doctor, who saw him on one occasion when he was perhaps apparently normal, for most of these patients had lucid periods There was, however, a growing practice, which the Board encouraged, for the medical superintendent, on the admission of a patient, to discover the name of his family doctor if there was one, and inform him briefly as to the nature of detention and invite him, if in the neighbourhood of the asylum, to come in and discuss the case It one who paid was done in every instance

The question of patients sent out on trial was next discussed SIR F WILLIS said that in the year 1922 23 the number of patients from borough and county asylums sent out on trial was 5,525, a large number had to return to the institution In regard to the adequacy of accommodation, he expressed the view that mental hospital accommodation was inadequate that in a short time the position would be serious, not to any undue increase in insanity, but to the growth of population

The CHAIRMAN thought it might be necessary to recommend a policy which since 1890 had arrested the growth of the population If fifty five licensed houses were sufficient in 1890 a larger number might be permitted now SIR F WILLIS said that the licensed house was a very useful institution almost always well managed

The witness was next questioned about medical certificates He said that there were very few misdemeanours in the asylums under the Act, but difficulty did arise through medical practitioners withholding certification of one of the primary facts in order to avoid the stigma of detention The practice of evasion of the Act, and of many such cases the Board of Control have no knowledge The practice of the Board of

such a case would be to apply to the Lord Chancellor for an order

The CHAIRMAN said that of course the circumstances might vary infinitely. This matter would be considered by the Commission at a later stage in connexion with voluntary treatment. He went on to refer to insane persons in workhouses. What was it that determined whether a patient found himself in a public asylum or in a workhouse? Sir F. WILLIS said he was afraid it was largely accident.

The CHAIRMAN said that the asylum provided a means of treatment and possible cure. Workhouse institutions were not the proper place for the reception of patients likely to improve under treatment. If they must be used it should be for chronic and hopeless cases. Sir F. WILLIS said that his Board would welcome consideration of this matter by the Commission. He felt that at present the best use was not made of the total accommodation. The CHAIRMAN thought it also might be desirable to have a more extensive series of regulations pertaining to lunatic paupers in workhouses affording them the same protection and facilities for making complaints as in the case of patients in other institutions.

Sir F. WILLIS, in reply to further questions, said that the Board had no statutory powers in the appointment of medical and nursing staffs or the arrangement of dietary. It could make recommendations.

Dr. BOND, at the request of Mrs. Matthews, described what happened to a patient on arrival at an institution. A preliminary physical examination directed specially to cleanliness and to marks of injury was made while the persons who had brought the patient remained on the premises. The patient was then put to bed for a week at least and an elaborate examination was made probably by more than one doctor. The cerebro-spinal fluid would be examined, a blood count made, the temperature recorded, and so forth, and he statement of the mental and bodily condition of the patient was sent to the Board of Control. The examination was repeated at monthly intervals certainly for the first three months and probably for the first year, and later at quarterly intervals. There was no rule that the physical examination must be repeated, but there was a rule that all changes must be noted. He added that mechanical restraint was now very rare in asylums.

Sir HUMPHRY ROLLESTON asked what happened if one of the medical certificates on which the patient was detained was found to be out of order and the certifying doctor could not be found—that is, was out of the country. Dr. BOND said that if the certificate was essentially faulty the Board would declare the order invalid and start again, if it was merely a technical fault the order might remain.

Sir H. POLLESTON asked how often it happened that the second certificate—the first having been given by the family attendant—was by a recognized expert in mental disorder. Dr. BOND said that this depended on the locality. In the metropolis it frequently happened that the second certificate was given by a well known specialist. He added that faulty certificates were extremely few compared with the hundreds of thousands of proper certificates that came to the Board, and that the medical profession as a whole had nothing to be ashamed of in the matter of certificates.

Sir DAVID DRUMMOND asked whether medical officers in mental institutions had sufficient clinical experience. Was it necessary for them to have had a training in a general hospital? Dr. BOND said that the Board had recommended such training some years ago, and had also urged mental hospital authorities to have in addition to their resident staff certain consulting physicians (not mental specialists) and gynæcologists and so forth.

Sir D. DRUMMOND: But you do not suggest that it should be a *sine qua non* that the asylums officer shall have had special clinical experience?

Dr. BOND: We should like to enforce it at once if it were practicable, but I do not think we could get the doctors. It happens quite often now that *visiting committees do not* get sufficient applications. But I think that the great majority, if not all, are capable of making a good general examination.

Sir D. DRUMMOND: Do you recognize that it is very desirable for every medical officer to have a special training in psychiatry?

Dr. BOND: Not necessarily before appointment, but before he gains any position of seniority.

The CHAIRMAN, at the request of a representative of the National Society for Lunacy Reform (who said that he had thirty witnesses he wished to call), put some questions to the witness. He asked how frequently the Board of Control had to investigate cases of cruelty.

Sir F. WILLIS said that the Board received a great many complaints chiefly from patients themselves, generally in letters. The cases were always investigated sometimes by inquiry on oath, and in very few instances—perhaps one in the last three years—were the charges found to be substantiated. In one case only in 1923 a prosecution was instituted against an attendant who was convicted of striking a patient and fined £2.

The CHAIRMAN: How many cases are brought to your knowledge in which there has been cruelty, but dismissal or some other disciplinary action has been taken instead of prosecution?

Sir F. WILLIS: Very few cases, half a dozen a year at the outside. All allegations are followed up, and in one rare case when the visiting committee did not prosecute the Board of Control prosecuted.

The CHAIRMAN: If the patient is ill treated his position is a difficult one; he may not have anyone to appeal to.

Sir F. WILLIS: He could always appeal to the doctor, and if competent to write, he could write to us.

The CHAIRMAN: Have you ever heard of cases in which the patients were too frightened to complain?

Sir F. WILLIS: That has been stated but not substantiated.

The CHAIRMAN: Such a thing could conceivably happen.

Sir F. WILLIS: Occasionally the Commissioners in going round are apprised of some case, and hold an inquiry then, and if the circumstances are very special a sworn inquiry.

The CHAIRMAN next asked whether the medical practitioners referred to in various sections of the Act need have any special qualification.

Sir F. WILLIS said that in most Acts of Parliament it was assumed that the practitioner knew everything about medicine. He added, in further reply, that the number of persons who had been discharged from detention on the ground that they were no insane when admitted was very small. He had no experience of an case in which person not insane had been wrongly detained in asylum. He regarded the existing machinery in the matter of certification and provision with regard to detention as adequately safeguarding the liberty of the subject, but if any additional precaution could be suggested they would be welcomed. He stated further that with regard to curative treatment in mental hospitals his Board had no responsibility—it acted only in an advisory capacity. The responsibility for the treatment of each individual must rest with the medical officer of the institution. If the Commissioners found an institution which was lax in this matter it would report to the committee of the institution concerned and would investigate further at the end of a short period. The Board could not require that an additional doctor should be appointed or a laboratory provided, but it could and did bring pressure to bear on the medical superintendent and in the case of a public asylum on the local authority.

This concluded the examination which had lasted eight hours of the members of the Board of Control, and the CHAIRMAN stated that they would be called again before the end of the inquiry.

Sir CLAUDE SCHUSTER, permanent secretary to the Lord Chancellor, gave evidence on the legal position of the Lord Chancellor in lunacy matters. He said that the Lord Chancellor's Visitors numbered three—two medical men and one lawyer—and they had to visit at stated intervals all lunatics found by inquisition and others in which property the Lord Chancellor had an interest, and they had to pay special visits when required to get specific information. Their interest was enlisted in individuals, not in institutions. The Lord Chancellor's department had also to deal with letters from lunatics which were numerous and lengthy. Some lunatics wrote every day to the Lord Chancellor voluminous essays on their delusions. The witness found it extremely difficult to answer the question whether the jurisdiction of the Lord Chancellor was of any value. It depended on the constitution of the Board of Control. He thought that the Board of Control should include the very highest mental authorities, especially on the subject of lunacy. It was also essential to have on that body an adequate representation of the legal mind, because medical men looked at these matters from a special point of view. Those who like himself had to read a number of medical certificates felt that while the honesty of the certifier could not be doubted the document failed to meet the lawyer's requirement because of the inadequate selection and arrangement of facts. Doctors were not trained to express themselves in a way that carried conviction to the legal mind. He did not question the conclusion of the certificates only the exhibition of the grounds which the practitioner set out. The medical man looked at the matter from the point of view of cure, but the question which the lawyer had to decide on the certificate was whether or not the person should be detained.

The CHAIRMAN: We can hardly expect every practitioner to go through a legal training in order to learn how to prepare a piece of evidence. But in Scotland at any rate all medical men take a course in forensic medicine.

Sir DAVID DRUMMOND: They do in England also.

The inquiry was adjourned until October 21st, when the evidence of witnesses for the Ministry of Health will be taken.

British Medical Journal.

SATURDAY, OCTOBER 18TH, 1924

MENTAL DISORDER AND THE LAW

The report published this week (p 707) of the discussion in the Section of Neurology and Psychological Medicine on certification in mental disorders from the medical and social aspects merits the close attention of the medical profession As one of the speakers, Dr G W B James, observed, the subject has assumed fresh importance owing to the appointment of the Royal Commission on Lunacy and Mental Disorder, which has now begun its sittings, and it should be the aim of all doctors, both special and general, to evolve clear cut and constructive criticism of the existing law

One matter which must be less vaguely stated than hitherto concerns the type of mental illness which it is considered should be treated without certification in its early stages Dr Henry Yellowlees, who opened the discussion, pointed out that a true borderland case does not often become insane—and presumably he here refers to the psycho neurotic—and that a mild or incipient case is by no means necessarily a curable one The most recoverable cases are undoubtedly, as he says, the acute forms of disorder patients who exhibit the most pronounced abnormality of conduct, and who are, therefore, the most certifiable There is certainly a general impression abroad that if mental cases were treated in the prodromal stages, before the disturbance in behaviour becomes pronounced and certification is inevitable, a number of cases would be cured, and the incidence of chronic insane in the asylums would considerably diminish This view would appear to be in some measure justified The general principle that the earlier a disease is treated the greater the possibility of recovery would appear to apply equally to mental disease as to other maladies It would, however, be a mistake to create the impression that there are specific cures for such conditions as dementia praecox and paranoia (which constitute the bulk of chronic asylum cases) if only they were taken in the early stages While an arrest or amelioration of such cases is obviously more likely if they are taken in the early stages, yet it must be remembered that an exact diagnosis and definite prognosis is extremely difficult in incipient psychoses

We do not think, however, that the plea for the treatment of mental cases without certification should be based upon promises of a dramatic diminution of cases needing permanent control in asylums There is no experience upon which to base such a promise, and a decrease in the incidence of insanity must ultimately depend upon the degree to which the principles of mental hygiene are disseminated amongst the community as a whole To agitate for an alteration of the law in order that cases described under such vague terms as "mild" or "early" may be treated without certificate would hardly seem to be justified The psycho neuroses, mild depressions, psychopathies, and nebulous types with vague psychotic symptoms would appear to cover the cases included under these terms, and there is nothing in the law to prevent them being treated without certificate at present It is true that there is a lamentable absence of homes to which such patients can be sent, but some do exist, and there is no legal barrier to their multiplication Many patients are treated, of course, as voluntary boarders, and, as we pointed out in a recent issue, there is no reason why the public mental hospitals should not be permitted to admit cases on a voluntary basis, the principle having been already admitted in one area It is thus not so much for mild and incipient cases that a radical amendment of the law is necessary, but rather for the acute cases, in which the symptoms are often of extreme severity

A statistical survey of the patients discharged as recovered from the mental hospitals reveals the fact that a large proportion were under certificate for less than six months, this period including the stage of convalescence, part of which is often spent at home on trial Furthermore, a considerable number of the recoveries are found to occur in patients who exhibit extreme restlessness, stupor, resistiveness, and confusion, so that they are definitely certifiable and cannot be treated away from home without legal sanction Such cases are due to a variety of causes—childbearing, lactation, influenza or other toxic illnesses, the stress of adolescence or the climacteric, and environmental difficulties They are, in many instances, recoverable in the full meaning of the term They often do not relapse, and lead perfectly normal and useful lives after discharge It cannot be denied that certification inflicts a very real hardship in such cases, and it must be remembered that these acute and recoverable psychoses occur in patients as young as 17, in women beginning their married life, and in persons in the prime of life holding responsible positions, all of whom are definitely handicapped in after-life by having been certified as insane We are in agreement with Dr Bedford Pierce that for such cases certification could be deferred safely, provided that there was no concealment and the hospital or place of treatment was properly equipped The restraint applied to persons suffering from the acute psychoses would be similar to that applied to the subject of a pneumonic or typhoid delirium, and both groups of mental illness would necessitate similar modes of treatment

There can be little doubt that in the future there will be an explicit recognition of the fact that, from an administrative standpoint, acute mental illness and chronic insanity involve two distinct problems Acute mental cases require a hospital, in the ordinary meaning of the term, for their treatment—a hospital differing only in structure from the general hospital, in which the whole resources of modern medicine are available for the treatment and investigation of the patients A hospital in the above sense is not required for the treatment of the majority of chronic mental patients What they need is a home in which they can be as happy as possible in view of their psychic disabilities With such patients every endeavour should be made to provide occupation, amusements, as much freedom as possible, and skilled medical treatment in the case of illness There should be strict differentiation between the sick, the degraded and disturbed, and the quiet and peaceful patients, so that those who are able to appreciate the amenities of life shall have nothing to jar on their susceptibilities Actually it is in these directions that progress has been made, and there is no question that the change in the methods of treatment since the lunacy laws were formulated has been very remarkable Whenever possible the recent admissions are treated in separate

hospitals apart from the chronic cases and every effort is now made to abolish the prison like features which characterized these institutions when different conceptions of mental disorder prevailed

It is on the basis of knowledge acquired by those who are accustomed to deal with mental cases that an amendment of the law is seen to be necessary if further progress is to be made That the duration of many cases of insanity is brief, that the attack is curable and leaves no traces of abnormality on the personality and that such patients are amenable to the same methods of treatment as are applied to other illnesses, are facts that should now be recognized by the Legislature, as also the fact that the conditions which made the provisions of the present lunacy law necessary no longer exist It is only when acute early and recoverable cases are treated apart from irksome legal formalities that the stigma which is now attached to the subject of mental disorder—and indirectly to his relatives—will be removed and it is only then that the public will learn to look naturally on mental disorder as a disease which, like all other diseases is open to cure amelioration, or progressive advance according to its nature and intensity

NOTIFICATION OF PUERPERAL SEPSIS

In April last the Ministry of Health published an elaborate report on maternal mortality by Dame Janet Campbell, senior medical officer of health for maternity and child welfare to the Ministry[1] we gave an account of it in our issue of April 12th (p 682) and set out fully the recommendations with which it concluded One of these recommendations was that in view of the *unsatisfactory results of the present notification* of puerperal fever it should be considered whether amendments are desirable in the existing legal provisions for notification in order to increase its practical utility a matter in which it would be useful to consult a competent medical body such as the Obstetrical Section of the Royal Society of Medicine" This invitation has been accepted, and the Sections of Obstetrics and Gynaecology and of Epidemiology and State Medicine of the Royal Society of Medicine have arranged a joint meeting with the Society of Medical Officers of Health on Thursday, November 6th to discuss the notification of puerperal sepsis The officers of the Obstetrical Section consider it very desirable that the views of those engaged in general practice as well as of obstetricians and medical officers of health, should be expressed during this discussion, and any general practitioner not a member of the sections or the society mentioned will be welcomed as a visitor and asked to take part in the discussion

Another recommendation of the report had reference to the need for improvement in the quality of professional attendance To attain this it was advised that the education of medical students in the principles and practice of obstetrics and gynaecology should as recommended by the General Medical Council be improved, and that midwives should be better trained by requiring a longer period of teaching prior to certification, and periodical post certificate courses of instruction As a corollary it was recommended that there should be closer co operation between the medical practitioner and the midwife and between the professional attendants and the local authority Preventive midwifery under the local authority should it was thought comprise the ante natal and post natal care of all pregnant women by the professional attendant as far as possible the establishment of maternity centres and the provision of maternity beds including observation and isolation beds for the treatment of complicated cases of midwifery and for the accommodation of women whose circumstances do not enable them to be confined easily and suitably at home

It was further recommended that all maternal deaths due to childbirth and all cases of puerperal infection, whether fatal or not should be investigated by the medical officer of health The final recommendation referred to the provision of special nourishment for necessitous, expectant and nursing mothers, to the desirability of extending sickness benefit during pregnancy, under the National Insurance Acts and to the need for widespread educational propaganda by official and voluntary agencies Sir George Newman in his prefatory note to the report pointed out that steps had already been taken by the General Medical Council the Central Midwives Board the local authorities and the Ministry of Health to deal with most of the points made in the recommendations but observed that there was need in almost all directions for further development of such arrangements

A few weeks afterwards the Scottish Board of Health issued the report of a Departmental Committee which it had appointed to inquire into the incidence of puerperal morbidity and mortality in Scotland with special reference to the conditions contributing thereto and to suggest any remedial measures A full notice of its arguments and recommendations was published in our issue of May 31st (p 961) and this article may be consulted with advantage in view of the coming discussion The Scottish committee urged the importance of ante natal care and the need for more systematic practical training of the medical student and discussed the problems presented by the education of the pupil midwife the maintenance of the midwife and the proper functions of local maternity hospitals In the same issue of the JOURNAL we took occasion to discuss the subject in a leading article (p 969) It was there observed that in the view of the Scottish committee—that the services of the trained midwife and the doctor are complementary—were accepted it seemed clear that the charge of normal labour would in future be more and more transferred to the midwife the duties of the medical practitioner being rather those of ante natal examination, and of passing patients as normal or, if abnormal of referring them to maternity homes, and of exercising general supervision

The joint meeting on November 6th will commence at 8 p m at the house of the Royal Society of Medicine (1, Wimpole Street, W 1)

PARLIAMENT AND VACCINATION

On September 13th (p 482) we commented in these columns to the new Vaccination Order issued by the Minister of Health and to the attitude of the vaccinationists towards the Minister He is now receiving from them exactly the kind of thanks or his concession to their demands might have expected had he known them better In their official organ they say frankly that whatever has come or may be hoped is unfortunately unable to pressure And as they have exercised pressure After receiving

[1] Ministry of Health Report No 40 Maternal Mortality By Janet Campbell M D M S London H M Stationery Office To be obtained through any bookseller Price 2s

a second letter from the League," and another, at the instance of the League, from the Labour party's executive committee, "Mr Wheatley let it be known that if the League continued to press the matter he would be willing to restore the Form" Thereupon another League letter was sent to him, "and a few days later Mr Wheatley issued his Order" But as for Mr Wheatley himself, his views, whether for or against vaccination, are 'without value or importance" Especially "his readiness, as avowed to Mr Abbott, to favour compulsion for everyone in face of an epidemic is thoroughly exasperating, and shows him to be equally ignorant and wrong-headed on the subject"

The British Medical Journal has, of course, nothing to do with party politics, but from the spectator's point of view there is a striking resemblance between the attitude of the extremest Russian Bolsheviks to Mr Ramsay MacDonald and that of the Anti-vaccination League to Mr Wheatley Clearly he is not an anti-vaccinationist, and he should begin to realize that no half-way concession will suffice to placate such a cult His knowledge of Glasgow compels him to believe in vaccination for the control of small-pox, and that belief condemns him in their eyes, so that while they accept all he gives them they continue to denounce him, and they deliberately make public the means they have used to effect their purpose, whatever the influence of that publicity may be on Mr Wheatley's reputation in politics Meanwhile the Minister of Health determinedly holds his peace on the merits of the matter, and just before the dissolution flatly refused to rescind the Order This refusal to be drawn into discussion was perhaps his most politic course in the circumstances He knows he has made a blunder, and he acts on the old adage, "Least said soonest mended" But the lesson, it may be reasonably assumed, will be remembered by him, and he will not be in a hurry again to try to reconcile the irreconcilable

Now that a general election has come upon us, the machinery of the Anti-vaccination League is doubtless working at full speed to entrap candidates who may make pledges about the Vaccination Acts in the hope of securing votes from persons who, in the narrowness of their outlook, put aside great national and imperial questions and concentrate on the one limited subject of the vaccination law Candidates, if they have time in the turmoil of the contest to give any real attention to the matter, should be warned by Mr Wheatley's unhappy experience Whether he ever gave a definite pledge we do not know, but if not his treatment by the League is all the more a warning of what may be expected

Recently in the newspapers there has been some protest in advance as to replying to sets of questions on many matters which, if or when the time comes for Parliament to deal with them, should be decided on their merits, in accordance with relevant circumstances and considerations Candidates will be wise to accept the advice given by Mr Baldwin in the House of Commons last March not to answer *questionnaires* at all—it is perhaps significant that those who issue such documents have to go to a foreign language for a term A firm refusal to commit himself hastily may lose a candidate a few votes here and there, but the display of caution and strength and independence will count for far more than easy or thoughtless pliability in the estimation of electors capable of weighing up the qualities of those who appeal for their support

THE MAUDSLEY HOSPITAL

The first annual report of the superintendent of the Maudsley Hospital is one of very special interest Fifteen years have passed since the munificence of the late Dr Henry Maudsley rendered possible the building of a hospital for recoverable cases of mental disease At first the difficulty of finding a suitable site, and later the war, delayed the fulfilment of his project, but the delay was not without gain, for powers were meantime obtained under the London County Council Act, 1915, allowing patients requiring treatment to be admitted at their own request and not under certificate This would have had Dr Maudsley's cordial concurrence, enhancing as it undoubtedly does the opportunity for the early study of mental disorder and its treatment under conditions the most favourable to recovery The further question arose whether any other than voluntary patients should be admitted, and it was decided to restrict the admissions to patients of this category, so that no certified patient is accepted at the Maudsley Hospital, nor is any patient ever certified there This latter provision was bound, of course, to give rise to some little difficulty, owing to the fact that a voluntary patient has the right to leave within twenty-four hours after giving notice to that effect Since this may happen in a case where there has been a sudden change for the worse, it is an essential condition of admission that some responsible party should agree to take care of the patient in such a contingency This same party likewise guarantees the payment of hospital charges These charges vary according to whether the patient has or has not a legal settlement in the County of London If he has, the charges are according to means, if not, the full maintenance rate, amounting to about £5 a week, must be paid The question of medical suitability also arises, it can generally be decided by a telephone conversation with the practitioner, but in any event the decision as to suitability rests with the medical superintendent Formalities are reduced to a minimum, and details of the steps preliminary to admission have been widely circulated The Maudsley Hospital has two chief purposes—research into the causation of mental disease and into its early treatment These are not coincident, but are not necessarily mutually exclusive Cases are accepted often because of the unique opportunities they present for study of their causation, quite apart from their chances of recovery Such facts have to be borne in mind when the results of treatment are examined The report is cautious in tone and comprehensive, and Dr Edward Mapother, the medical superintendent, claims little Bearing in mind the dual purpose of the Maudsley Hospital, he has observed a judicious discrimination in the selection of cases, nor does he hesitate to say that even though the aim of the hospital were a single one—treatment to recovery of the maximum number—good results would indicate mainly the capacity for prognosis of the medical staff Many forms of treatment have been pursued Especially interesting was a case of bronzed diabetes with profound confusion, where treatment by insulin brought about practically complete physical and mental recovery, although there was no marked hyperglycaemia but definite glycosuria The malarial treatment of general paralysis of the insane has been carried out in several cases without any conclusive results Various forms of psycho-therapy have been employed Dr Mapother, although sceptical of the tenets of any recognized school, none the less insists that this method yields results that cannot otherwise be obtained Research work was handicapped at the outset by the necessity for organizing the general work of the hospital, but later numerous investigations have been carried out under the direction of Dr Golla, director of the pathological laboratory These include the determination of basal metabolism in cases of

dementia praecox, investigation of the oculo-cardiac reflex, some abnormality being noted in the majority of cases of the psychoses, and testing of the emotional response as indicated by the psycho-galvanometer. The researches are of great promise, and are being actively prosecuted. During the first year 1,012 cases have attended the hospital, of these 452 were admitted as in patients. Of the latter the majority came via the out-patient department. About half the total number of admissions were sent in by general practitioners after consultation with the superintendent. This shows how real an advantage the Maudsley Hospital is to the busy practitioner. Altogether the report makes stimulating reading. The work which is being undertaken in the Maudsley Hospital is one of singular promise.

PROTECTIVE GLASSES

THE subject of the presidential address of the new president of the Ophthalmological Section of the Royal Society of Medicine, Sir Arnold Lawson, of which a report will be found at page 719, is of very general interest and one on which the opinion of many practitioners must frequently be asked. Magazines, newspapers, and railway posters are all advertising the advantages to eyesight of special forms of spectacle glass designed to protect the eyes of the wearer from the "damaging" effects of ultra violet rays, and many persons are becoming obsessed with a fear of the mysterious influences of these rays. These rays are potent when they are in any volume, as in the rays of an exposed arc-lamp, or in the clear atmosphere of the high Alps. In such situations exposure without protection is likely to cause injury to both eyes and skin, but the effects are transient, and these special conditions are rarely met with by the ordinary city dweller. For him the murky atmosphere of the smoke laden canopy of heaven cuts off far too much of the virtues of sunlight—a fact that has been brought home to us by recent researches upon the pathology of rickets. For the great majority of the population specially tinted or protective glasses are quite unnecessary; where spectacles need to be worn the ordinary glass of the lenses gives sufficient protection. If in the neurasthenic more is needed, then the protective, but scarcely tinted glass devised by Sir William Crookes gives all the additional defence needed. When genuine pathological processes occur within the eye further protection is both valuable and necessary. For the special conditions of exposure to sunlight at high altitudes, or for the industrial risks of furnace workers, welders, and the like special forms of protective glass are imperative. It is to be hoped that the address of Sir Arnold Lawson will do something to dispel a fear engendered by the commercial exploitation of scientific advances designed for definite purposes. So far as town dwellers are concerned far greater benefits are to be found in the proper arrangement of lighting both natural and artificial. Conditions have been vastly improved in schools but it is still common to see clerks working at desks facing the window, and therefore in conditions that would try perfect eyes. In the opposite case windows are often dirty or overshadowed by screening walls, so that on even bright days artificial light has to be used to supplement the inadequate daylight. Further the spread of the use of high power illuminants excellent in themselves, has brought real disadvantages to the office workers, since these new lights are used in ways which produce a maximum of irritation to the eyes instead of a maximum of comfort. New wine must be put into new bottles, and with new lamps new shades *new hangings* and new arrangements are needed or else the eyes of the users will be as uneasy as the old wine skins strained by the fermentation of the young wine. Much of the demand for protective glasses comes from clerical workers and it arises from the neglect of these simple precautions in lighting, the use of the protective glasses does not, in fact, attain the end sought.

MEDICAL CONFERENCE IN HONG KONG

AT the invitation of the Hong Kong and China Branch of the British Medical Association, the China Medical Missionary Association will hold its biennial conference at Hong Kong from January 21st to 28th, 1925. Delegates have been invited from Great Britain, India, and America, and it is hoped that eminent authorities in different branches of medicine and surgery will address the conference. Board and *lodging for* members is being provided at a nominal cost and private hospitality will be available to a limited extent. It is worthy of special note that the two bodies about to meet in conference—the Branch and the association—were founded independently in the same year—1886—and that the University of Hong-Kong in whose buildings the *meetings* are to be held had its origin in the foundation of a missionary hospital. Western medicine was first introduced into China in the early part of the *nineteenth century* and the progress subsequently made has been almost entirely due to the work of medical missionaries. Since 1915 a considerable amount of assistance has been received from the China Medical Board of the Rockefeller Foundation, the chief work of the latter being the creation of the present Peking Union Medical College which was originally a missionary effort. The China Medical Missionary Association was founded in 1886 and has at present about 600 members, chiefly British and American missionaries and certain Chinese and other doctors who are in sympathy with its work. The association meets biennially in different cities of China but this is the first time it has visited Hong Kong, the South China branch of the association having its headquarters at Canton. Since 1887 the missionary association has published the *China Medical Journal* which until 1915 was the only journal of Western medicine appearing regularly in China. In the latter year however a National Medical Association of China was established for Western trained Chinese and a medical journal was associated with it. The Hong Kong and China Branch of the British Medical Association was first established in 1890 but it naturally grew out of the Hong-Kong Medical Society which was founded in 1886 with the late Sir Patrick Manson as its first president. It now has 158 members of whom 29 are resident in Hong-Kong. In 1887 the Alice Memorial Hospital was opened under the auspices of the London Missionary Society and the Hong Kong College of Medicine was founded with Sir Patrick Manson as its first dean. From this College of Medicine came the University and its medical school in 1912 with the first appearance of its medical society's journal the *Caduceus* in 1922. The conference provides an excellent opportunity for this school to demonstrate its possibilities as a centre of the practice of Western medicine more particularly in South China. These possibilities have already been recognized by the Rockefeller Foundation which provided 750,000 dollars for the endowment of full time chairs in medicine surgery gynaecology and obstetrics. The China Medical Board contributes also towards the scholarship fund for students enabling them to come from the Canton Christian College to the University for their medical course. The conference will provide *moreover* an opportunity for the British and Chinese in Hong Kong to appreciate something of what is being done for Western medicine in China and will encourage them to make some contribution in return for the commercial and other benefits which they derive from residence in Hong-Kong. It is proposed to place the sectional meetings of the conference under the control of a joint chairman and to appropriate the British Medical

Association and the China Medical Missionary Association The following sections have been formed general medicine, therapeutics, pathology, general surgery, ophthalmology, ear, nose, and throat, radiology, obstetrics, anthropology and anatomy, physiology, hygiene and public health, parasitology, naval and military hygiene In the great hall of the University arrangements are being made for the exhibition of instruments, drugs, medical publications, food materials, and hospital apparatus The joint honorary secretaries of the conference are Professor J L Shellshear of the University of Hong-Kong, representing the British Medical Association, and Dr James Maxwell of Shanghai, representing the China Medical Missionary Association

A PATENT METHOD FOR THE ENCOURAGEMENT OF SCIENCE

Dr Fritz Warschauer, who describes himself as a patent agent of Berlin, requests us to publish a note of a lecture he gave lately to the Deutsche Naturforscher und Aerzte at Innsbruck We will do so with pleasure, because the matter of the lecture must have been no less interesting to the natural philosophers and doctors of Innsbruck than Dr Warschauer's English report is to us It appears that in this lecture "the bacteriology has been, for the *first* time, discussed minutely from the point of view of the German Patent Act" The lecturer showed "on hand of numerous specifications that the German Reichs-Patentamt has, in acknowledging a justified claim, granted patents for bacteriological process" Formerly an invention was considered patentable in Germany "only if it related to mechanical or chemical treatment or working up of raw materials, viz, if by technical means a technical effect was obtained" It seems, however, that "in praxi the Reichs-Patentamt has given up this antiquated notion, probably in consideration of the development of the bacteriologic science, and by a recent decision it has expressly acknowledged that processes and methods are patentable which utilize the vital proceedings of nature" We are sorry that Dr Warschauer has not sent us the list, "combined by the lecturer," showing that "many famous scientists and leading chemical factories are inventors and proprietors of the bacteriological patents" Our ill-paid scientists should be grateful to Dr Fritz Warschauer for his message of hope Why not draw royalties instead of invoking State assistance? The bacteriologist of the future, lapped in luxury, deriving from a patent cure-all polyvalent serum an income that even Jackie Coogan might envy, will look with pity upon the wasted opportunities of pre-Warschauer workers And he will have the added satisfaction that, by retiring early on the proceeds of his world-wide patent, he will make room for other aspirants to fame and fortune, thereby encouraging the pursuit of science

INTERNATIONAL CONGRESS OF THE HISTORY OF MEDICINE

As we announced briefly last week, the fifth International Congress of the History of Medicine will be held at Geneva from July 20th to 25th, 1925, under the patronage of the Medical Society of Geneva The president of honour is Sir D'Arcy Power, K B E (London), and the vice-presidents of honour are Dr P Capparoni (Rome), Dr D Giordano (Venice), Dr E B Krumbhaar (Philadelphia), Dr Ingwal-Lavastine (Paris), Dr J G de Lint (The Hague), Dr A Pater (Geneva), Dr J D Rolleston (London), Dr Charles Singer (London), Mr C J S Thompson, M B E (London), and Dr Tricot-Royer (Antwerp) The president of the congress is Dr Charles Greene Cumston (Geneva) The vice-presidents are Dr Ernest Wickersheimer (Strasbourg) and Professor Andrea Corsini (Florence) The general secretaries are Drs A de Peyer and Emile Thomas (Geneva) The treasurer is Dr Edouard Schauenberg Subscriptions for members will be 15 Swiss francs, for associates 10 Swiss francs, these should be sent to the treasurer at the office of the general secretariat, 20, rue General Dufour, Geneva Members will be entitled to a copy of the *Proceedings* of the congress when published A preliminary programme of the proceedings will be issued about December 1st, 1924, and can be had on application to the general secretariat A cordial invitation is extended to members of the medical profession interested in the subject to become members and take part in the sessions of the congress

PETER LOWE'S "CHIRURGERIE"

An exceedingly rare Elizabethan surgical textbook is being sold at Messrs Sotheby's on October 28th—namely, a copy of the first edition of "The Whole Course of Chirurgerie, wherein is briefly set downe the Cause, Signes, Prognostications and Curations of all sorts of Tumors, Wounds, Vlcers, Fractures, Dislocations and all other Diseases, usually practised by Chirurgeons, according to the opinions of all our auncient Doctours in Chirurgerie Compiled by Peter Lowe, Scotchman, Arelian, Doctor in the Facultie of Chirurgerie in Paris, and Chirurgian ordinaire to the most victorious and christian King of France and Navarre" A note on Master Peter Lowe, with a reproduction of his portrait at the Royal Faculty of Physicians and Surgeons of Glasgow, appeared in our issue of July 8th, 1922, (p 59) Only one other copy of this edition of 1597 is on record, and only two copies exist of the second edition of 1611, one of which is in the British Museum It was printed in London by Thomas Purfoot, and incidentally throws light on the bibliography of another book, Norden's "Speculum Britanniæ," published in 1593, for a leaf of this latter book is bound in at the end of Peter Lowe's textbook, which makes it very probable that Purfoot printed for Norden also, whose well known "Speculum" contains no clue to the printer At the end of the textbook proper Lowe appends several pages of the "Presages of the Divine Hippocrates" He dedicated the work first to King James and also to Lord Sempill, both dedications are dated April 20th, 1597

THE GENERAL ELECTION

As the nominations for the forthcoming general parliamentary election take place on Saturday, October 18th, it has not been possible to compile a complete list of medical candidates We understand that the following members of the medical profession will offer themselves for election

Dr C Addison (Lab) *Hammersmith South*
Dr Ethel Bentham (Lab) Islington East
Sir George Berry (Con) Scottish Universities
Sir *John Rose Bradford (Con)* } University of London
Dr T G Bushnell (Lab) }
Dr E G Graham Little (Ind) }
*Dr W A Chapple (Lib), Dumfries
Dr Stella Churchill (Lab), Hackney North
Dr R Dunstan (Communist) Birmingham West
*Dr Walter E Elliot (Con) Glasgow Kelvingrove
*Dr T E Fremantle (Con), St Albans
Dr O Glee on (Lab) *Portsmouth North*
*Dr L Haden Guest (Lab) Southwark North
*Mr Somerville Hastings (Lab) Reading
Sir *Henry Jackson* (Con) Wandsworth Central
Sir Richard Luce (Con) Derby
Dr J J Lynch (Ind Lab) Walsall
Dr I H MacIver (Lab) Argyll
Dr H B Morgan (Lab), Camberwell North West
Dr A Salter (Lab) Bermondsey West
Dr Laura Sandeman (Con) *Aberdeen North*
Professor Thomas Sinclair (Con), Queen's University, Belfast
*Dr G F Spero (Lib) Stoke Newington
Dr T Watts (Con), Manchester Withington
*Dr J H Williams (Lab), Llanelly
*Lieut-Colonel T S Bethamp Williams (Lab), Lambeth, Kennington

Candidates who sat in the recent Parliament are indicated by an asterisk

UNIVERSAL CURES, ANCIENT AND MODERN

BY

A. J. CLARK, M.C., M.D., F.R.C.P.,

PROFESSOR OF PHARMACOLOGY, UNIVERSITY COLLEGE, LONDON

Any general discussion of quackery is far too big a subject for a single paper.

This paper is confined to certain universal cures brought forward by men of considerable medical knowledge who nevertheless appear to have genuinely believed that they had discovered a universal cure for disease. Most of the cures discussed appear to have some real or supposed connexion with electrical phenomena.

Francis Anthony Mesmer

During the last two centuries there has been a general tendency for universal cures to be connected with electricity and magnetism. About 1750 a widespread idea was established that the mysterious new *phenomena of electricity* and magnetism were manifestations of a force which, if properly applied, would act as a remedy for all known diseases.

This vague popular idea was first *exploited on a large scale* by Francis Anthony Mesmer (1733-1815). Mesmer started with an interest in astrology and wrote his thesis for the M.D. of Vienna on the subject of the influence of the planets on the human body. He next spent many years experimenting with the Imperial astronomer Pere Maximilian Hell on the effects produced by magnets when applied to the diseased body, and he attained considerable success by practising in Vienna along these lines. He discovered, however, that he could influence patients without magnets and even without touching them, and thus developed a form of treatment by suggestion. Professional jealousy drove him from Vienna, and he went to Paris in 1778, where he attained sensational success by methods which really consisted in treatment by suggestion reinforced by an imposing display of imitation electrical apparatus. Like most enthusiasts who believe that they have discovered a universal remedy, Mesmer expressed the utmost contempt for orthodox medicine, and resolutely refused to submit his apparatus to any form of test.

The measure of his success in Paris is indicated by the fact that he was supported by a large number of doctors, headed by Dr. D'Eslon, President of the Medical Faculty of Paris, moreover, he is said to have made £16,000 in fees in two years, and the Government offered him a pension of about £1,000 a year provided that he established a clinique magnetique and instructed three State appointed persons in his methods. Mesmer refused this offer, but in 1783 a number of well-to-do persons subscribed a total of about £14,000, in return for which Mesmer agreed to instruct them as pupils.

Mesmer therefore enjoyed the support of a large and powerful section of Parisian society, but his methods soon found imitators, and the wholesale exploitation of hysteria forced the Government into action. A strong commission was appointed, including amongst its members Lavoisier and Franklin. After five months' inquiry the commission decided that Mesmer's apparatus was incapable of producing any electrical or magnetic effects. They admitted that patients were profoundly affected, but thought that more harm than good was likely to be produced, and recommended the suppression of Mesmer's practices.

The most interesting points about Mesmer's success are as follows: he really did discover something—namely, the extraordinary effects that suggestion can produce in disease on the other hand, he firmly convinced both himself and his patients that a complex and imposing apparatus, his famous tub, possessed marvellous powers of healing by the magnetic force it exerted, and yet the tub was incapable of producing the slightest electrical effect of any kind. The general similarity between Mesmer's tub and Abrams's oscilloclast is very striking.

James Graham

James Graham had a fair knowledge of medicine; he studied at Edinburgh and may have taken his degree there. He picked up some knowledge of electricity in America. In 1780 he returned to Europe, and practised in London and Bath, and also at Aix-la-Chapelle. He exploited electricity as a cure for all diseases; he apparently had a fair amount of knowledge of the subject, for he had constructed to his own design some unusually large electric friction machines, and apparently produced quite impressive sparks.

He converted a large house in the Adelphi in London into one of the most remarkable palaces of quackery that has ever been known. This Temple of Health was furnished throughout with most lavish ornaments; statues, armour, painting, immense pillars and globes of gold, remarkably arranged plates of burnished steel, and electrical apparatus of every description were included in the decorations. The general effect was intensified by soft music from an invisible orchestra and perfumes of spices. The chief shrine of the temple was the Grand Apollo Apartment; this contained a throne, and above the throne a crown was suspended from which electric discharges could be produced. Patients were treated by being placed on the throne and having electric discharges played upon them.

In addition to the above methods of treatment Graham claimed that by means of electricity he could extract from drugs ethereal extracts that were cures for all known complaints, and which were indeed practically elixirs of life. For a certain supply of these medicines the modest fee of £1,000 paid in advance was demanded, and it is known that this sum was paid by several persons.

Graham was a tall, and one may of commanding presence, and he reinforced the attractions of his electric sparks by providing a strong sex interest. He gave a lecture on the cure of sterility with an entrance fee of six guineas, and a contemporary reports: He uses the plainest language in dealing with the parts concerned with generation, yet ladies as well as men crowd to hear him without scruple. Graham issued his lecture in pamphlet form at the price of a guinea, and even by modern standards it must be ranked as remarkably obscene.

Extra attractions also were provided at the lectures; for Emma, the future Lady Hamilton is said to have served as a nude model in his lecture on health. In addition Graham's temple contained the famous piece of apparatus, his Celestial Bed. This was an ornate couch around which electric discharges could be produced. The bed was guaranteed as a cure for sterility, and couples were allowed to use it on payment of a fee of £50.

There is, however, another side to his character; for he gave very sound hygienic advice to his patients, recommending cold baths and fresh air, ideas that were then extremely uncommon. Moreover, Graham was a religious fanatic, and throughout his writings one finds declamations against war and appeals for religious toleration blended with a kind of deism.

In the late years of his life Graham became insane. Some called him half-enthusiast, half-knave. Graham is chiefly interesting as a blend of religious enthusiast and obscene charlatan, and his writings are a proof of how complex and contradictory are the motives actuating the unbalanced minds of the discoverers of universal cures.

Elisha Perkins

The vogue of Perkins's tractors is, I consider, the most interesting example on record of the sudden rise and fall of a universal delusion regarding a universal cure.

For many years Perkins, who was the son of a doctor and a graduate of Yale, lived as a successful practitioner in Connecticut; he was a man of fine physique and remarkable for his untiring energy. He was respected by his fellow practitioners and acted as chairman of the local medical society. His strong personality and desire to do his professional duties soon brought him a high position amongst his patients, and he was very impressed by the amount of benefit that patients appeared to derive from his mere presence.

Magnets and lodestones were still believed to be endowed to possess medicinal powers—for example, the Royal Sick

---

Abstract of Presidential Address to the Section of Therapeutics, Royal Society of Medicine, October 14th, 1924.

of Medicine in Paris concluded in 1779 that magnets were therapeutic agents of no ordinary efficacy Perkins concluded that his personal influence was due to some occult magnetic force, and made experiments in treatment by the application of magnets and metals to the diseased parts His son, in a short biography, states

"These experiments, however, for many years added but little to the information he obtained from the first observation The extreme uncertainty attending the results of all his experiments sometimes almost inclined him to think that this supposed discovery was all a fallacy, and the effects ascribable to imagination In the year 1796 however he acquired some new ideas on the subject which led to the discovery of the unequivocal influence of certain metallic substances on diseases, and the invention of the metallic tractors"

These tractors were two sticks of metal, about as thick as lead pencils—one looking like brass and the other like steel They were made of a mixture of various metals, including silver and gold, and were sold for five guineas a pair Perkins believed that these tractors were capable of benefiting or curing practically all diseases both of men and animals Their method of application was as simple as the tractors themselves, for it consisted in simply drawing the tractors downwards over the affected part for twenty minutes, and no previous knowledge was apparently needed for their application

Perkins, who was a man of great energy and enthusiasm, travelled up and down the country demonstrating his invention He demonstrated the use of the tractors in numerous hospitals, and his methods were endorsed by numerous doctors and professors, and he received the support of many of the leading men of the country, such as governors and judges His methods naturally met with opposition, and in 1799 he was expelled from the Medical Society of the State of Connecticut on the ground that his patenting of his invention was contrary to professional etiquette

In 1799 yellow fever ravaged New York, and Perkins went there to combat the epidemic with his tractors, he caught the disease, and died, after five days' illness, at the age of 59 This ending proves conclusively Perkins's absolute sincerity Yellow fever is not a disease which anyone would encounter with a remedy which they knew to be worthless, but one would have imagined that his death would have raised doubts concerning the efficacy of his tractors The vogue of the tractors was, however, undiminished They had been introduced to Denmark by the wife of Major Oxholm, a Danish diplomat, and were investigated by the leading professors of surgery and medicine in Copenhagen, who issued a report stating that "The arguments against animal magnetism would not apply to Perkinism, that the discovery was of importance to the healing art, and that it merited the thorough attention of physiologists" The report contains accounts of the cure of gout, rheumatism, and epilepsy and other diseases, and it was translated into German by Dr Tode, physician to the King of Denmark

England was, however, the seat of the greatest triumphs of Perkinism The movement here was directed by Perkins's son, who came here about 1797, he was not a medical man, but possessed the instincts of a sound advertising agent The tractors had a tremendous popular success, and were used with equal efficacy on humans, horses, and pet dogs In 1804 a Perkinean Institute was founded in London, with Lord Rivers as president The institute enjoyed the support of eight professors of four different universities, twenty-one physicians, nineteen surgeons, and thirty clergymen It is said to have had a larger endowment than any other hospital in London

There was, of course, opposition to the prevailing craze In 1799 a Dr Haygarth of Bath performed a few experiments with the help of some friends They explained fully and impressively to a group of hospital patients that a miraculous new remedy had been discovered, and proceeded to treat them with imitation tractors made of wood The results were striking, most of the patients declared themselves immediately cured or greatly benefited, although one or two stated that the pain of the treatment was so intense that they could not endure it The hospital was soon surrounded by an excited mob demanding treatment with the new remedy The experimenters apparently had a rather difficult and dangerous time when they had to explain that the whole business was a hoax

The opinions of Perkins, junior, on this criticism are best indicated by the following headings of the pamphlet he published in reply

"All these artifices having in view to prove that the tractors acted on the imagination, the author presented as an extinguisher of such pretensions, above an hundred cures on infants, horses, epileptic fits, tumefactions and inflammations

"Among the vouchers to these facts were eight professors, in four different universities, eighteen regular physicians, fourteen surgeons, thirteen clergymen, etc

"Very strange that the diminutive looking tractors should be pretended to have any influence on the imagination of a patient, from the confidence they might create

"The writers in the *London Medical Review*, whose supply of bread depends on a continuance of the use of medicine in preference to this simple remedy, devote thirty six pages to dissuading the public from trying metallic tractors

"Reason for attaching far greater confidence to the testimony of the numerous respectable and *disinterested* characters adduced in this work than to the *interested* writers on the contrary side of the question"

It will be observed that the arguments for and against universal cures have not altered appreciably during the course of one hundred years The cures always fail completely when subjected to any adequate control or test, and the reply to such criticisms is always the same a high-minded philanthropist is working for trivial pecuniary rewards to provide mankind with a universal safeguard against disease, and this urgent and all-important work is being obstructed by the selfish opposition of a profession which fears that its livelihood is being endangered

I hope that I have indicated in this discussion the respect that I feel for Perkinism—the respect that one owes to any perfect example of its kind, even though it be but an example of human folly Perkinism was a true artistic triumph in that a maximum effect was produced with the simplest possible technique Half the civilized world was induced to believe that any disease could be cured by drawing over the diseased part two sticks of metal for twenty minutes I do not think that this record in delusions has ever been rivalled, and I doubt if ever it will be surpassed

Twenty years later, when the bubble had burst, it still seemed incredible to one who remembered the craze that the whole thing should have been a complete delusion The idea that an enormous effect can be produced without any rational cause is offensive to the ordinary beliefs of mankind, and with every craze one hears the identical argument that there must be something in it because it is so widely believed and supported

Perkinism is a remarkably clear-cut demonstration of the falsity of this assumption There was no discoverable germ of truth in its practice, it achieved enormous popularity in a few years—testimonials as to its miraculous powers were supplied by thousands of persons, including many of the highest professional attainments, finally it fell into utter disrepute with equal suddenness Like an epidemic the craze rose and raged and waned, without any apparent reason for its course The only reason for the belief and for the disbelief seems to have been the rise and decline of a wave of delusion, and the whole history of the process shows how completely judgement can be inhibited by mass suggestion

Albert Abrams, 1863-1924

Dr Albert Abrams was a medical graduate of Heidelberg, and he practised for many years as an orthodox practitioner in San Francisco About fifteen years ago he began to seek for a universal cure for disease, and first brought forward the cult of spondylotherapy This was a blend of osteopathy and chiropractic with some of the more glaring absurdities toned down We cannot tell what form spondylotherapy would finally have assumed, for its development was dwarfed by Abrams's next step—his discovery of the famous electronic reactions

The electronic reactions of Abrams are obtained by two

machines—one a diagnostic machine and the other a curative machine. The diagnostic machine was the original and fundamental "discovery," and I shall only deal with this at present.

The apparatus consists of a contrivance or dynamizer in which is put the drop of blood to be tested; this is connected through four rheostats to the forehead of a healthy medium. The presence of the blood in the dynamizer causes changes in the area of stomach dullness of the medium, these changes are modified or abolished by varying the resistances in the rheostats. With this mechanism Abrams claimed that he could determine the age, sex, religion, race, and nature of disease of the patient providing the drop of blood. Moreover, the diagnosis could be made from either a drop of blood or the handwriting of the patient. For example, the diseases suffered by Dr Johnson were determined from a signature of the great lexicographer. I think you will agree that these claims are remarkable, for in the first place there appears to be no conceivable relation between Abrams's theories and any of the known laws of physics, chemistry, or physiology. Secondly, the claims appear to be of such a nature that their truth or falsehood could be demonstrated by a few hours' test.

An examination of Abrams's publications shows that his ideas developed step by step from some theories put forward by a Mr Baines in 1913. Mr Baines was an electrician who detected the well known skin currents by means of delicate galvanometers and thought that their measurement would provide a means of diagnosing and locating disease. This theory, advanced by an electrician with no knowledge of medicine was developed by Abrams, who had some knowledge of medicine, but apparently no knowledge of electricity. This accounts for the final bizarre form of his theories. Naturally Abrams was able to get equally good results whatever modifications were introduced into his apparatus, and his followers have found the same. On one occasions wires have been disconnected unknown to the operator, the reactions have been unaltered, the reason being that electronic vibrations need not travel along wires. On other occasions specimens have been removed from the dynamizer without the knowledge of the operator and the reactions have continued, the reason is that the electronic vibrations are so powerful that they set up similar vibrations in all material with which they come in contact, and these after-effects can only be destroyed by waving a magnet over the spot.

Abrams soon passed from the diagnosis to the treatment of disease. Starting from the fundamental idea that disease is due to derangement of the vibration rates of the electrons he sought a method of altering these rates. He noted the fact that a glass resonator could be shattered by a sufficiently strong sound of the wave length to which it vibrated. He therefore devised his oscilloclast, a form of electrical interrupter. The oscilloclast is intended to pass into the body electronic energy of the same wave length as the erring electrons in the diseased tissue. Some of the early forms of the oscilloclast were the subject of adverse criticism because an investigator found that one of them contained four closed circuits and did not furnish sufficient energy from its terminal leads to deflect even the most sensitive galvanometer. This error has now been adjusted, and the patients under treatment can lie and watch an electric light twinkling at the correct vibration rate. Abrams was an American Jew, and naturally, almost instinctively he made a commercial success of his discoveries. As I have pointed out in other instances of universal cures, the fact that they consider their discoveries priceless and charge accordingly is no evidence that they do not believe in the discoveries.

Abrams's theories violate all the known laws of physics and physiology even more completely than did the theories of Perkins, and I do not propose to attempt any criticism but will pass on to describe the progress of electronic therapy. As already mentioned, the diagnostic claims of Abrams are such that they admit of proof or disproof with extraordinary ease.

Abrams's doctrines were naturally disbelieved by the rest of the American medical profession as a whole, but since he held a reputable position in San Francisco he was given opportunities to demonstrate the truth of his extraordinary claims. He always refused, and soon there arose a sharp antagonism between him and his followers and the rest of the American profession.

The offer of two machines, one a universal means of diagnosis and the other a universal means of treatment, naturally proved attractive to many persons, particularly to osteopaths, homeopaths, and chiropractors. The great expense of the machines rapidly provided a strong commercial interest in support of the electronic method, and public interest was sufficiently aroused for a leading popular scientific paper, the *Scientific American* to offer to undertake an impartial investigation of the whole matter. This proposal was endorsed by the electronists in general and Abrams in particular. The committee of investigation found, however, that it was practically impossible to arrange even the simplest tests and the investigation which they imagined would take a few weeks took nearly a year. The final report has just been published and it simply states that as far as the committee can ascertain the so-called electronic reactions do not even exist.

The following criticism by the *Scientific American* appears to be completely justified:

> If in the opinion of the electronic workers their methods are insufficiently developed at this time to pass a most elementary test such as we propose then in good faith and through honesty of purpose they should without delay suspend their present electronic practice. They should tell their patients that they are not sure just what they are doing. After all human life is too precious to be the subject of raw experimentation of something worse than that as the case may be.

The only means by which the electronists can make this position satisfactory is by submitting their methods to some properly controlled impartial test. Such tests ought to commence with the diagnostic technique, for this is much the easiest to test and this was Abrams's original discovery. The methods of treatment were later developments from the original diagnostic methods. There is now an Electronic Society, I believe, and therefore there is no obvious difficulty in organizing satisfactory and final tests.

The general argument of the electronists is that tests are superfluous since they can support the truth of their claims by innumerable testimonials from patients cured of every kind of disease and that they are so busy doing *good* that they cannot waste time in proving what they already know to be true. Unfortunately for this argument, history fails to record any variety of quackery that has failed to obtain testimonials from persons who have genuinely believed themselves to have been benefited by its method.

The history of Perkins's tractors surely teaches as clearly as anything can that thousands of honest people can believe sincerely in a universal remedy for disease which is absolutely worthless. As I have said it is difficult to offer any criticism of Abrams's theories because these bear no relation to any of the known laws of physics and therefore there is no basis for argument. They are just as completely outside the realm of inductive science as were Mesmer's tub, Graham's ethereal essence, Perkins's tractors or Hahnemann's tinctures and like these other cults the electronic reactions have acquired a body of devout followers most of whom are probably fervent and sincere believers.

In all cases ancient and modern we find that the followers of the cult, if left to themselves, can perform miracles daily but under impartial inspection cannot satisfy the most elementary tests. There is really nothing strikingly new or remarkable in the present electronic vogue; dozens of similar crazes have arisen in the past and will arise in the future. These universal cures simply represent the old quest for the elixir of life in a new form, and arise to satisfy the fundamental craving of the mass of humanity for a miraculous cure for disease. Science has nothing to do with these cults and they are scarcely influenced by its progress, and since the type of mind that produces them and accepts them both remain constant one finds from century to century that remarkable analogies between succeeding crazes which I have tried to indicate in this paper.

THE OLYMPIA MOTOR SHOW.

NEW STYLE MOTOR CARS FOR MEDICAL MEN

By H MASSAC BUIST

The International Motor Car Show was opened under the patronage of the King at Olympia, Kensington, on October 17th, and will remain open until the evening of Saturday, October 25th, Sunday excepted The charge for admission on Monday, Tuesday, Wednesday, and Thursday will be 5s, on other days 2s 6d The hours are from 10 a m to 10 p m on each day This is the eighteenth show organized by the Society of Motor Manufacturers and Traders, and it is a little unfortunate that again this year it is taking place during the period of a general election

Visitors will find that drastic reductions have been made in the cost of the cars shown, these reductions have been effected not only to clear stocks, but also because many individual enterprises have embarked on quantity production to an extent hitherto unknown in British practice The reductions are the more remarkable because the British trade is heavily taxed and is badly situated with regard to labour costs The trade in the United States is protected by a 25 per cent import duty, while the French industry is protected by a 62 per cent tariff, and wages in France are something less than a third of those paid in this country It is encouraging to find that in many instances British-built vehicles are being sold at prices which are competitive with foreign products This applies not only to the so-called "light cars," but to middle-size cars also It is quite a mistake to accuse the British motor industry of want of enterprise, this exhibition shows that it has answered the challenge created by the unequal competition due to the tariff laws of other countries The result of the broad-minded policy pursued by the Society of Motor Manufacturers and Traders is that the British public, including, of course, medical men, can choose from the cream of the output of motor factories of foreign countries as well as of their own All that is asked by the British industry in connexion with the present show is that, given equivalent merit at approximately the same prices, the home-built car should be chosen, thereby giving employment to British labour

New Chassis Types

This year's show is remarkable in that its prime interest lies not in the introduction of quite new chassis types but in the fact that it is representative of the current motor manufacturing enterprise of all parts of the world The reasons for the relatively few changes are twofold In the case of many manufacturers their existing models have been developed in detail because they were introduced as entirely new types either one, two, three, or four years ago Having proved successful, the practical thing to do is to refine and otherwise perfect them as opportunity offers and further experience is gained The other reason, unfortunately, is that there remain, quite inevitably, a number of car types, made both by foreign and by home builders, which have been over-produced and which have to be cleared There is a sound reason for the introduction of each of the new cars There has never been more commendable designing in general than characterizes the novelties introduced, and this applies to the evolution of the small-engined car, as distinct from the small car of cramped accommodation—two absolutely different things, which American experts still fail to appreciate but which should be fully grasped by even the non-technical British public, albeit this is not yet always the case

New Cars

The entirely new home-built types presented for the first time at a motor exhibition are as follows

20/40 h p £20 tax straight eight cylinder 2 493 c cm Belsize with four wheel brakes chassis £695 saloon landaulette £1,050

£16 tax 1 991 c cm overhead valve six cylinder engined Marlborough sports type chassis with front wheel brakes £400

18/35 h p £19 tax overhead valve 2 540 c cm six-cylinder engined Talbot car with internal expanding front wheel brakes on a six brake system four speeds, right hand controlled, complete with five seater all weather equipment, £825, seven seater saloon landaulette £1 090

12 h p £12 tax 1 699 c cm side valve four cylinder engined Arrol-Johnston, with four wheel brakes four seater complete, £360

15/45 h p £16 tax 1,991 c cm six-cylinder engined Calthorpe chassis with Rubway contracting band front wheel brakes chassis £318

45 h p £52 tax 8,458 c cm double sleeve valve six cylinder engined, 18 ft 4 in wheel base 60 in track Daimler chassis with four wheel brakes—the largest chassis yet standardized—£1 400

14 h p £14 tax 1,944 c cm four cylinder engined Gwynne chassis £360, four seater £410

9/20 h p £9 tax overhead valve water cooled four-cylinder 1,074 c cm engined Rover one door four seater complete with electrical engine starting and car lighting as well as all weather equipment, three speed gearbox, worm drive, balloon tyres, £185, three door four-seater on longer wheel base, with *de luxe* body, £215

14/45 h p £14 tax four cylinder overhead valve (overhead cam shaft driven) 2,120 57 c cm engined four wheel braked Rover, with right hand controlled four speed gearbox, bevel axle driven, enclosed internal expanding mechanically controlled four wheel brakes, with Dunlop balloon tyres and a mile a minute speed capacity five seater complete, £550

In regard to entirely new types from abroad the 15 h p sports type overhead valve engined Lorraine may be mentioned, each and all are meritorious cars of their kind, but relatively few of them concern the average medical man Of the Rover types, the earliest information was published in these columns last month when the chassis were described in detail For the medical man who wants great powers of acceleration and good hill-climbing capacity the Talbot is worthy of remark It is economical in fuel, tyres, and tax in relation to its performance and great durability It is by no means experimental, for it was designed by Mr Louis Coatalen, the Sunbeam engineer, and its main details are uncommonly like a more up-to-date version of the smallest six-cylinder engined Sunbeam car, which is not now listed The Talbot is built at Kensington by the new management, and it represents the latest practice of the firm, it is of a type which ought to restore it to the enviable position it enjoyed in the larger middle-size car market before the war

From Canada come the £22 tax 3,102 c cm overhead six cylinder monobloc engined Buick five seater, £395 with contracting hand front wheel brakes and balloon tyres, also the £23 tax 3,995 c cm side valve six cylinder engined three speed Studebaker with hydraulically controlled expanding shoe four wheel brakes, four or five seater, £415 complete

13/35 h p £13 tax 1,873 c cm four cylinder engined Triumph with balloon tyres Lockheed hydraulic four wheel brakes Lucas grease gun lubrication to the chassis, and Marles steering gear, saloon £495 complete

18/50-h p £18 tax 2 850 c cm four cylinder engined Swift with four speeds controlled by the right hand large diameter rear wheel brake drums equipped with two sets of shoes mounted side by side one pedal operating in synchronism with Perrot type front wheel brakes and the other (outer) set controlled by hand lever touring model £595 complete

America introduces the six cylinder Lockheed hydraulic four wheel braked, three speed, semi balloon tyred Chrysler touring type at £465, and the smallest four cylinder car made in the U S A, the 16/45 h p £17 tax 2,378 c cm Rollin designed by Mr Rollin White, of White Steam Car fame, with internally expanding four wheel brakes, balloon tyres, disc wheels, "one push" oil gun chassis lubrication, system three point rear suspension five-seater £343

From France comes the 15/50 h p £16 tax 2 484 c cm four-cylinder engined front wheel cum transmission internal expanding shoe braked Berliet chassis at £450 the 16-h p £16 tax 3,016 c cm four cylinder engined Chenard Walcker with no brake drums on the back wheels, all braking being through Hallot automatic servo on the transmission shaft and on the front wheels in synchronism, on a system which ceases to operate directly the wheels lose momentum, in other words, the moment the wheels become locked, the 20-h p 3 745 c cm overhead valve six cylinder engined Hispano-Suiza with the firm's distinctive four wheel braking system and the £12 tax 10-h p 1 552 c cm double-sleeve valve engined Voisin with exhaust vacuum controlled Dewandre front wheel brake system

Examples of New Price Scales

It may not be good policy to take a car in its first year of production unless it follows, in the main, a design of which the given firm has had long previous experience, and there-

fore embodies nothing experimental A medical man wants a car that is not merely low in price, but which will not cost him much in taxation the tyre, fuel and lubricant bills of which shall be moderate, which shall be a good hill climber, of reasonably good acceleration and equipped for all weathers Hitherto many a small car that has fulfilled most of the requirements has failed in regard to the accommodation for driver or passenger

It is in this connexion that the most all round progress has been achieved by the industry, as well as in reducing prices, this year Take Coventry's contributions alone, and observe the excellent fruit that the pioneer work of the Standard Company is bearing now in other directions That concern was the first to appreciate that when a small engine is put in a car, if that vehicle is to be useful it must provide full scale accommodation for driver and occupant This year we find among Coventry's product the 10-h p Singer, the 10 h p Swift, the 11 h p Hillman the 9/20-h p Rover, and so on, all marketed with greater accommodation That this applies also to Birmingham is shown by the developments in connexion with the 11/22-h p overhead camshaft driven overhead valve Wolseley, the accelerator pedal of which is now placed on the extreme right, thereby affording much more leg room Other

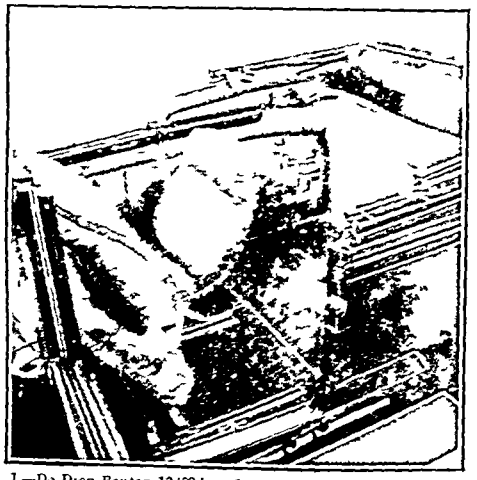

FIG 1.—De Dion Bouton 12/28 h p Coupe-cabriolet 2/4 seater Interior of bodywork showing occasional seats drawn forward

examples from various parts of the country could be cited, but a few illustrations of each point must suffice

It is highly satisfactory to note—and on this point the medical man should be careful to investigate for himself—that where chassis have been lengthened to provide more body space, generally they have been strengthened in section proportionately, this is essential Many chassis are made wider The practice of fitting balloon tyres to small cars is almost universal The popularity of the Dunlop cord type, which scores of manufacturers are standardizing, is observable Provided the steering is designed properly, this is the class of vehicle for which the balloon type of tyre is really needed, and on which it can be made eminently satisfactory In connexion with larger scale cars it is to be observed that America favours the use of the balloon tyre of the straight-sided variety, whereas few manufacturers on the Continent follow this example, though they are willing to supply such tyres as an extra to the buyer's order—in other words, on the purchaser's judgement, not on the manufacturers' Practically the same situation obtains in regard to the industry in this country This decision is not the outcome of lack of enterprise but has a sound basis The Belgian industry does an interesting thing in the case of some of the Minerva cars, which come under the heading of the full scale middle size car and which are equipped with what are styled "semi-balloon" tyres in other words, tyres that are of not exaggeratedly large section nor of pronouncedly low pressure

Moderate Prices

While in nearly all cases development in detail is shown, it may be seen in regard to the scale of accommodation, nevertheless the most important appeal is under the heading of price in which connexion we may take such well known all weather equipped types as the following and quote the figures to give an idea of the very widespread efforts that have been made to open a new series of possibilities to the medical man whose means are limited strictly

£12 tax 4 C £275 £12 tax Argyll-John on £360 Austin 8 seven £155 8 h p Power £160 Morris-Cowley 2-seat £175 9/20-h p Power seat at £185 10 h p Singer seat at £215 10-h p Swift 4 seat at £235 11 h p Standard with Kineton seat at £260 11 h p enlarged and widened balloon tyred Hillman saloon £335 11/28 h p Morris Cowley seat at all weather equipped with four wheel brakes £245 £12 tax 2-seat Bean £335 £10 tax 2-seat Pelsize £240 £11 tax 4/5-seat Bianchi £345 £10 tax 2-seat Bean £240 £11 tax 2 at Calcott £265 £11 tax 2-seat Caltelette £225 £8 tax 2-seat balloon tyred Citroen £145 £12 tax balloon tyred seat at Citroen £225 £11 tax 2-seat Clyno £175 £16 tax 5-seat Crossley £345 £6 tax 4-seat Daimler £860 £12 tax seat Darracq £425 £13 tax 2 3-seat De Dion Bouton £475 £15 tax seat De Dion Bouton £650 £14 tax Delage 5 seat £475 £16 tax 5-seat Delaunay Belleville £650 £24 tax 5-seat Dodge £525 £16 tax 4 5-seat Durant £160 £10 tax seat Enfield Alldays £350 £17 tax

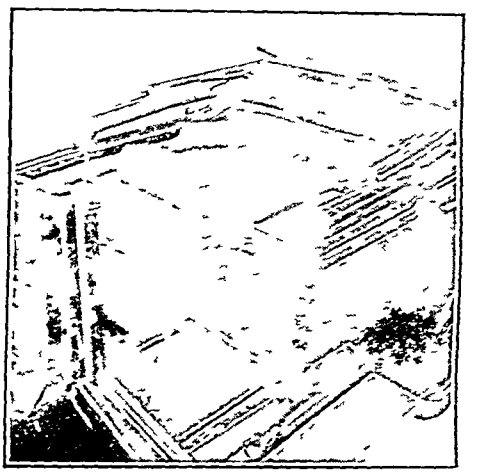

FIG 2.—De Dion Bouton 12 28 h.p Coupe-cabriolet Interior showing occasional seats folded back

six-cylinder Essex £295 £11 tax seat Fiat £540 £23 tax 4 5-seat Ford £125 £11 tax 2 seat Galloway £245 £8 tax 4-seat Gwynne £250 £11 tax 2/3-seat Hillman £358 £8 tax 2/3-seat Humber £240 £21 tax 5-seat six-cylinder Lorraine £645 £11 tax 2 seat McKenzie £250 £19 tax 5-seat Overland £165 £11 tax 4 5-seat Peugeot £295 £12 tax 4-seat Phoenix £365 £28 tax 5-seat F W B Studebaker £415 £12 tax 4-seat Sunbeam £570 £17 tax 5-seat F W B 14/40-h p Sunbeam £625 £9 tax seat 10 23-h p Talbot £345 £14 tax 4 5-seat 14 40-h p Vauxhall £625 £11 tax 2-seat Wolseley £275

The Doctor's "Occasional Four" Coupe

De Dion Bouton introduces this year on a 12 28-h p four wheel brakes chassis, an occasional four coupe type of good interior illumination and notably easy access The rear beside the driver is tilted forward when it is desired to enter or to leave, the rear collapsible seats which are accommodated very neatly when not in service Ample accommodation is afforded for luggage when the rear seats are not being used It is to be noted that the height is of fashion of rear suspension by cantilever springs is employed Front wheel brakes have been incorporated in De Dion practice for some seasons This type of all-ender body affords two really roomy front seats sliding independently of one another on rails and locked at once in the position most comfortable to the occupant of each

The doors are uncommonly wide one being provided on each side, so that it is possible to have direct access to the different seats The front seats are built on the scale principle

so that a light push on the back rest causes each seat to slide forward towards the windscreen, where it lies folded up out of the way, leaving a gap of 18 inches through which to pass to the rear seats. Even in the case of the driver's seat, which, of course, is impeded in its forward motion by the presence of the steering pillar, nevertheless 14 inches of space is available if it is desired to have access to the rear seat from his side. In the rear of the body are provided two folding seats each about 14 inches square. When not in use these slide out of sight into pigeon-holes in the rear squab. Those riding in these seats can face either forward or vis-à-vis. Even when two passengers occupy the rear seats still the luggage capacity is adequate, a hinged flap in the boot giving access to a tunnel which is the full width of the body and open at its inner end. Four frameless plate-glass windows, controlled by easy lifting handles and self-locking when in closed position, are provided, together with a V screen. This, and all other De Dion bodies, are equipped with rubber insulating buffers interposed between the body and the chassis round the dash to prevent rattle. Nine barrel-shaped buffers are employed on this particular body, and ten circular rubbers are interposed between the dash and the body proper. The mounting of coachwork on rubber buffers, originated by Lanchester, is somewhat widely exploited this year.

Coachwork Schemes

That metal will not be superseded and that wood will be the material which will be eliminated presently from body-building is illustrated by the methods in which the Austin bodies are built of steel. The steel body has been standardized by Dodge in America for years, and it is interesting to note that in the new American Rollin car a three-point flexible suspension with single-point attachment at the rear is used to solve the problem of chassis twist, which causes noise in covered bodies. To-day, not only does it not cost much money, but men who know how to wish down a car without destroying the varnish are not available, because the younger generation has not been trained to this. Hence the interest of what is, in effect, a system wherein the transatlantic manufacturer, turning out, possibly, a million against our hundred thousand, would have no advantage.

With few exceptions manufacturers do not introduce larger engined models than formerly, though there is the case of the Daimler, also the Belsize "straight-eight," which latter, however, has only a 2-litre engine. Buick introduces a 20-h.p. six-cylinder type to supplement its existing 27-h.p. type, and it is significant that the 2,300 c.c. four-cylinder engined Rollin car, brought from America by the designer of the erstwhile White steam car, with four wheel brakes, is called the smallest four-cylinder engined car made in the United States, a point that gives us at once the difference between American and European engine practice, since that engine is three times as large as some of the well established European types.

Four Wheel Brakes

Though in France I have been working on the idea for twenty years, yet to-day, when most manufacturers are actually giving attention to it and a large number are actually standardizing some scheme, I realize that not one car builder in three who standardizes cars with four wheel brakes to-day is doing so on lines that are desirable as regards safety, economy, wearing life, and so forth. That ultimately four wheel brakes will be a standard equipment of all cars, including the lightest, because of them light road adhesion, is hardly open to doubt. It has taken more than ten years to get the light car accepted as a permanent type, and I have spent at least as long in advocating the possibility of fitting a small engine into a chassis which provides, nevertheless, full scale accommodation for the occupant. That work is coming to fruition this year in a general fashion, as many new style small cars listed are testifying. We must not expect to reach my ideal, of 1 cwt. of vehicle weight for 1 cwt. of passenger weight transported, for, possibly, twenty years. The vehicle having 1 cwt. of car per 1 cwt. of passenger will be all-metal built—

Governing Factors in Improvements

The work of perfecting engines and rendering them flexible goes ahead. Therefore by conventional methods it is possible to make simpler gearboxes, and hence there is less urgent need for torque converters to displace them. In like fashion the coming of the balloon tyre may in part hold up chassis development, for it succeeds in disguising the faults of suspension in certain cars, especially as the average user has not the advantage of handling a couple of score, or more, different makes of motor carriages every year, and thereby keeping in touch with the latest achievements, and so ever resisting his standard of judgement. Many a car that seems to steer well and to ride smoothly to the average user is, as a fact, a third or fourth ranker in classification under those heads. If we could enable buyers—alike among existing motorists who desire new machines, and among entirely newcomers who do not understand the niceties of cars—to know exactly the relative merit of each car in its category, there would not be a dozen types of cars on the world's market to-day, and their users would have the best in each class at a lower price than they have to pay for the worst car to-day, because production of the leading types of each class would be on a scale representing in each country the most economical conditions of production.

Engine volume is no guide to engine performance, and, in general, there is one standard of engine performance in the New World and quite another in the Old. Much more is expected here of an engine than in America. Therefore, to consider an American car cheap because it has an equivalent nominal engine rating with a European is to be led astray. The way to achieve satisfactory motoring is to get the machine that fulfils requirements, irrespective of design. In this country many firms have re-rated their engines—for instance, the Humber, Singer, and the Wolseley—this year. The overhead valve gains many converts, by far the most general system of operation being by a camshaft in the crank case working vertical pushrods and rockers, though there are notable exceptions. Other engine developments include the general spread of

General Tendencies

The influence of the British Empire Exhibition over much of the detail of design, alike of chassis and of bodies, is shown at this show. Instances are afforded by the 14/40 Vauxhall, the 18-h.p. Armstrong-Siddeley, the Empire Talbot-Johnston model, the redesigned 14/40-h.p. Sunbeam, which is now fitted with six wheel brakes and is a reproduction on a lesser scale of the remarkable 20/60-h.p. type, in all of which vehicles there is ample ground clearance, generous provision of body width, and low centre of gravity. The practice of providing proportionately much wider doors is almost universal. It is to be found even on such cheap constructions as the 9/20-h.p. Rover, the 10-h.p. Swift, and the 10/26-h.p. Singer, and has been always a characteristic of Standard car practice.

Sometimes the widening of chassis is accompanied by the provision of larger brake drums, illustrated in the smaller Singer and the 9-h.p. Rover models. Again, Standard is one of the firms that has not hesitated to borrow a distinct from racing practice by using large diameter brake drums, to the great gain alike of efficiency and economy both of brake linings and of tyre wear. In regard to engine practice, we find the use of the Lanchester vibration damper for balancing the secondary forces in the crank case coming into general practice alike in England and America, because it is commercially a practical proposition.

forced feed lubrication To this end too, filters have been furnished to the pumps and aluminium pistons are gaining in favour We no longer consider it necessary to raise the bonnet to start an engine, even in cold weather hence the general use of stranglers operated from the dashboard

There is a distinct movement, particularly on behalf of the British industry, to provide change-speed gear and hand brake control levers on the driver's right, this being in response to public demand, instances among small cars are the 10-h p Swift and among middle size, the 14/40-h p Vauxhall Among the middle car classes there is a tendency for British practice to revert from the American to the Continental system in providing four speeds forward, despite the fact that no engines are more flexible than the best English makes, for the reason that America cannot get the Continental scale of power output for volume which our manufacturers do, and that in general, Continental manufacturers do not provide the flexibility which our best manufacturers do because abroad the demand is mainly for an engine that shall function much like an aircraft power plant —namely, that it shall be able to run slowly as well as at high speed on the straight, clear roads In this country on the contrary, with its twenty miles an hour speed limit and its tortuous roads, it is impossible even if the law be ignored, to go in average country at the full capacity of an engine for more than a few hundred yards at a spell Therefore we want flexibility always The use of four speeds assists a flexible engine, particularly in hill-climbing wherein cars in this country are at a disadvantage because our hill roads are ill graded, whereas hill and mountain roads abroad are graded scientifically Therefore our hills are relatively more difficult to climb and it is better to have a greater number of speeds Nor do drivers in general object to changing gear as much as they were wont to do because of the increasing use of the plate clutch also of the provision of better profiles for gear teeth and lighter controls and the use of clutch stops, whereby double clutching can be eliminated The plate clutch is a British invention which is being taken up now all over the world

Better Chassis

In regard to chassis construction, the fabric universal joint for the propeller shaft—the hardest worked of any on a chassis—finds an increasing number of users on the great saving of expense some manufacturers who have used these joints in the past are making them of more generous proportions this year, a point which newcomers would do well to note Apart from cheapness, these joints have the advantage of not needing lubrication

Disc wheels are not making much progress in use on small cars, but an interesting example of their introduction to some of the most expensive vehicles is afforded by Lanchester Many manufacturers are using lower frames an instance is the Austin 20-h p model with Carlton body giving a large, well lit interior of exceptional proportions and very easy of entrance The 14/40-h p Sunbeam has proportionately a much lower hung chassis of greater width and excellent lateral stability

Maintenance is facilitated, as well as efficiency ensured, by the very pronounced increase in the use of grease gun lubrication for chassis a practice which will unquestionably become universal because it ensures grease being applied to all the points of a chassis which need it, and very rarely get it, unmixed with road dust or grit, by the methods of oiling hitherto used This grease gun system is adopted by American and Continental manufacturers including Darracq, as well as by numerous English manufacturers

Front axles have undergone modifications in face of the introduction of front wheel brakes an instance is the 20-h p six-cylinder Wolseley which is of a correct section Examples of correctly designed axles in this respect include the 40-h p Fiat the 14/45-h p Rover, the 20/60-h p Sunbeam, and the 20-h p Lanchester—three distinct systems For the first time the 40/50-h p Rolls-Royce is shown with front wheel brakes of a very special design and fair performance, as I found in trial The firms marketing front wheel brakes as standard include Austin for all models, Lanchester the new 12-h p Arrol Johnston, as have the 14/45-h p Rover and many other quite new types Vauxhall extends the principle, hitherto standardized on the 30/98-h p type, to the 23/60-h p type Some manufacturers like to couple up the transmission with the front brakes, and to keep the rear wheel brakes independent In France there is the Chenard-Walcker chassis with no drums on the back wheels a scheme that has been copied in that point by one American manufacturer Front wheel brakes are optional on certain Armstrong-Siddeley cars on certain Crossley certain Daimler the 14-h p Standard, the 14/28-h p Morris-Oxford and on the side valve four- and six-cylinder engined Fiat models and among very many others

Prices of Foreign Cars

To show that reductions in prices are not confined entirely to British makers the 15/20-h p 2 litre engined Bianchi chassis is now listed at £395 the reduction of the different model complete with coachwork ranging from £80 to £160 The three-quarter English built coupe body on this is listed at £670 the four seater all-weather English body at £715 complete this is also the price of the English built four seater saloon Bianchi displays original practice in supplying forced feed lubrication to the gearbox gaining power and reducing noise The quite new 15/50-h p four cylinder engine is of the overhead valve type, and Perrot automatic type four wheel brakes are provided to the chassis on system that furnishes the car with six brakes in all Louis Penault one of the pioneers in standardizing front wheel brakes on really engineering principles employs them even for the £9 tax £250 8 3-h p three seater type now without any prejudice to the amplitude of the steering lock This small machine is also equipped with balloon tyres

Some Popular Cars for Medical Men

One of the comparatively few British firms to introduce entirely new chassis this year is Calcott whose 12/24-h p type is fitted with an all-weather equipped four-seater body at £375 and the four to five seater at £525 the three-seater semi-coupe costs £355 The design of the chassis does not differ from well proved practice the power being transmitted through a dry plate clutch to a gearbox giving four speeds forward controlled by the driver's right hand the back axle is driven by silent bevel gear The braking efficiency is proportionately much greater than on any former Calcott type The clean lines of the chassis are commendable, and it should have good wearing qualities This engine comes within the 2-litre category

The 11 h p Hillman engine has been developed in detail to meet the equipment of the car with balloon" tyres and of the new wider and more commodious coachwork provided A better system of lubrication by forced feeding is furnished for the power plant A gear pump is driven from the rear end of the cam shaft to ensure the circulation of the lubricant In place of a dipper stick for ascertaining the oil level a convenient two-level tap is fitted furnished with a handle placed accessibly above the tray between the bearer arms and the side of the power plant The equipment on this car is very complete including dash lamps licence holder petrol gauge air strangler on the dash carpets on the floor electrical Klaxon horn windscreen wiper hood cover spring gaiters by lamp lighting set, and so forth The four five seater all-weather body is available at £375 on this pattern

Standard's introduction of the Piccadilly four seater saloon on the 11-h p chassis at £275 represents a new note in values as does the £220 five seater all weather Kingston body on the same chassis The £14 tax four-cylinder overhead valve engined Standard chassis is listed at £225 and with Warwick all-weather body at £235 The Pall Mall five-seater saloon on the same chassis is £295 complete All 14-h p Standard types can be furnished with a system of front wheel brakes

The three-quarter coupe-cabriolet on the developed 10-h p Swift chassis is listed at £275 and the four seater or the two- eater with dickey on the same chassis at £255 in each case The wheelbase of this type has been lengthened by 9 inches so providing much more leg room and seating capacity The four seater model's present two doors each

of commendable width The running-boards have been brought much nearer to the ground, and valances added to fill in the space between boards and frame The springing has been developed to take the more commodious coachwork, and Hartford shock absorbers are standardized

Italy introduces the 15/50-h p £15 tax 2,294 c cm overhead valve four-cylinder engined Bianchi, with internal expanding front wheel brakes chassis £440, 4/5 seater complete £555, also the 50/100-h p £45 tax 7,372 c cm overhead valve eight-cylinder-in-line engined Isotta-Fraschini, with the firm's distinctive four wheel brake system chassis £1,395, 4/5 seater complete £1,750

Accessories

The Accessory Section is by no means the least interesting of the show It constitutes an exhibition which itself would occupy several days fully to investigate Though chiefly connected in the minds of the motoring public with the sale of cars and the building of high-grade coachwork for chassis, Mann, Egerton and Company exhibit also (Stand 369) much interesting garage and motor-house equipment, together with clever and attractive fittings for the car One is a neat smoker's companion For the thoroughly equipped garage there are bench milling machines, an air compressor and tank, a pressure cleansing tank, a mileage test tank, a grinding machine and attachments, an engine stand, a first-aid equipment, a wheel alignment gauge, and so forth The M E atomizing air valve, exhaust gas heater, petrol-oil cans, plug holders and cleaners, are other items of interest

Those who suffer from cold when motoring in winter should inspect the "everlasting foot warmer and foot muff," exhibited by A W Gamage (Stand 258) Of course, this firm shows also an extraordinarily complete range of motor equipment and accessories The Gemmy flooding-from-the-dashboard device for the carburettor, the Ford-Fixe combined exhaust and inlet washer, and a spare petrol can combined with the foot rest, are shown by Messrs Johnson, Neal and Co (Stand 375) Messrs S Smith and Sons (M A), Ltd (Stand 429), show the popular K L G sparking plug—used by practically all the competitors in important races—the need for which increases as standard motor car engine efficiency is improved "Rectaskid" is the name of a thin ball bearing inserted between two main leaves of each road spring the claim being that it reduces skidding, the principle will be explained to visitors at Stand 269

Electrical Apparatus and Tyres

The reputation achieved by Exide batteries is made plain by the exhibit of the Chloride and Electrical Storage Company (Stand 290) There is on view an interesting battery that has been in continuous use for twelve years, taken from the first Cadillac car equipped with an electric engine-starting car-lighting and engine-ignition system, this being the first firm in the world to standardize the electrical engine starter A redesigned model of the now long proved Lodge priming plug, with a number of distinctive features, is shown for the first time A new Lodge-Ford plug is among many interesting types that include the smallest sparking plug ever made (Stand 426) Examples of various types of Zenith carburettors, of which over 5 million are in use, include a special model made for rapid fitting to Morris Cowley and for Morris-Oxford cars Various technical improvements have been made in the 1925 Zenith, ensuring still greater efficiency and petrol economy, all these devices are now sold complete with filter under the float chamber and in an strangler over the inlet port, ensuring easy starting on the coldest morning (Stand 477)

The Dunlop Rubber Company's exhibit includes the low-pressure, large section "comfort" or "balloon" tyres evolved as a result of many years' experience, in the course of which admirable research has been used, instead of rushing on the market prematurely to meet an anticipated demand The Dunlop "wired-on" "balloon" tyre is claimed to be the safest large section type, and the security of the method of rim attachment is made plain by demonstration on the stand Chevrolet Swift, Vulcan, and such-like cars, with 31 in by 3½ in beaded-edge normal tyres, will take 31 in by 4·40 in "balloon" tyres without alteration of existing rims Of course, the firm continues to make its well known corded tyre types, both of the beaded-edge and of the straight-sided varieties Among the accessories marketed by this firm is a special jack for use with cars fitted with balloon tyres (Stand 500)

THE VOLUNTARY HOSPITALS IN GREAT BRITAIN.

Work of the Joint Council

The fifth annual report of the Joint Council of the Order of St John and the British Red Cross Society concerning the provincial hospitals of Great Britain has been published

Dr F N Kay Menzies, director of Hospital Services of the Joint Council, has collected in this report a huge amount of valuable information about the work of voluntary hospitals during 1923, and so follows the example of the late Sir Napier Burnett, who originally instituted the issue of these annual reports He draws attention to the fact that whereas in 1921 the ordinary income of the hospitals failed to meet the ordinary expenditure by £419,135, and in 1922 this deficit still amounted to £74,978, in 1923 the ordinary income exceeded the ordinary expenditure by £213,694 In 1920 only 44 per cent of hospitals had a surplus of ordinary income, in 1921 this percentage had increased to 51, in 1922 to 57, and in 1923 to 66

The object of the report is defined by Dr Menzies as being the presentation of the position of the provincial voluntary hospitals with reference to the facilities available for treatment, the extent to which they are utilized by the community, the annual cost of maintaining these facilities, and the sources and expenditure of the financial resources by which they are maintained Out of 755 hospitals, with 44,403 available beds, 710 hospitals, including 43,404 available beds, are reviewed in this report In the London area, which is not included, there are 116 hospitals, with 13,002 available beds, the total, therefore, in Great Britain is 871 voluntary hospitals, with 57,405 available beds With regard to the finances of these hospitals in 1923, the total expenditure was £6,381,115, and the total receipts £7,689,072 Of these total receipts £7,051,248 was raised by voluntary effort, the remainder being derived from public services (£550,918), and grants from the Voluntary Hospitals Commission (£86,906) These figures comprise both the ordinary and the extraordinary income and expenditure Dr Menzies remarks that it is now impossible for any person to maintain the old argument that the voluntary hospital system finds its justification in the fact that by it a vast amount of sickness and suffering is cured and relieved at little or no cost to the public purse He considers that it should be argued rather that the strength of the voluntary system and the real justification for its continuance should be based upon the fact that this immense volume of work is carried out more efficiently and more economically than it could be by any other known method or system Comparing the two years 1922 and 1923, it is interesting to note that in the former year 2,090,855 patients were treated at a cost of £4,946,299, whereas in 1923 2,861,306 patients were treated at a cost of £5,162,393 It is thence possible to estimate that the cost of a patient in 1923 works out at £1 80, against the cost of £2 40 in 1922

In an address delivered last June to the British Hospitals Association, Dr Menzies attempted to demonstrate the considerable growth of the responsibility of public health authorities in connexion with the provision of treatment for disease, and the full text of his address is published in the report He now draws attention urgently to the great need of providing greater facilities for treatment of ophthalmia neonatorum and infantile paralysis He refers to the report of the Departmental Committee on the Causes and Prevention of Blindness (1922), and suggests that it is almost a national scandal that ophthalmia neonatorum should be still responsible for approximately 30 per cent of all cases of total blindness in this country, not to mention the large number of cases of partial blindness The disease is eminently curable if prompt and efficient treatment is provided in the earliest stages, but, generally speaking, throughout Great Britain inadequate provision of this kind

is made Similarly, with regard to poliomyelitis he adds that the available hospital accommodation is seriously deficient, though there is evidence to show that the cases, if recognized at an early stage and submitted to skilful and prolonged treatment, will greatly benefit, whereas neglecting them results in irreparable and lifelong injury In his opinion, if the voluntary hospital system cannot cope adequately with these diseases, public opinion will insist upon adequate provision being made by public health authorities

An attempt was made during the year to estimate approximately the sum spent annually upon drugs in voluntary hospitals, and it is believed to be not less than £200 000 An article on economy in drugs and dressings, by Colonel J W Harrison, special medical officer for venereal diseases to the Ministry of Health, is published in the report Colonel Harrison, using the venereal diseases department of St Thomas's Hospital as an example, indicates that there is still considerable scope for economy in this respect without any sacrifice of efficiency being involved Dr Menzies urges similar conclusions in the case of tuberculosis dispensaries and in the case of private practitioners and suggests to hospital boards of management and their medical staffs that subcommittees might well be formed to investigate the question The main body of the report is devoted to statistical reports of the volume of work done in the voluntary hospitals, of total receipts and expenditure, of analysis of some of the sources of ordinary income, and analysis of the principal items of ordinary expenditure

Besides the special articles mentioned above, Mr J F Stone, accountant to St Thomas's Hospital contributes a statement of the principles upon which hospital accounts should be based, and Sir Francis Colchester Wemyss a member of the Joint Council, briefly surveys contributory schemes taking as examples two in operation at the Chesterfield Royal Hospital, in Glasgow the Radcliffe Infirmary, Oxford and the Royal Hampshire Hospital, Winchester

England and Wales

University of Durham College of Medicine

At the opening ceremony of the winter session of the University of Durham Newcastle upon Tyne, College of Medicine on October 6th, the address to the students was given by Sir Thomas Horder, Bt, of St Bartholomew's Hospital In the unavoidable absence of the President Sir David Drummond, the duty of introducing the orator to the audience was discharged by Sir Thomas Oliver In the evening Sir Thomas Horder was entertained to dinner by the staffs of the College of Medicine and of the Royal Victoria Infirmary The chair was occupied by Sir Thomas Oliver, who was supported by Mr R G L Mortimer and Sir Joseph Reed vice-chairman and honorary treasurer respectively of the Royal Victoria Infirmary In acknowledging the toast of his health, and after alluding to the pleasure of meeting men of the Newcastle School of Medicine, Sir Thomas Horder reviewed some of the methods of medical practice in vogue in these days He compared British with American methods, and discussed "group work" at length He did not altogether favour "group work," and he gave reasons for the opinions he expressed He thought that much more could yet be done in the way of post-graduate teaching He admitted that in London there were difficulties in providing the particular type of post-graduate instruction needed by medical men visiting this country from the colonies and from the United States He was in favour of a temporary interchange of teachers, and of a mutual interchange of clinical visits whereby physicians and surgeons might have the opportunity of seeing the patients in other hospitals, and the students be given the opportunity of observing how the diagnosis and treatment of disease might be approached from other standpoints than those with which their own teacher had familiarized them He himself had invited physicians from other institutions to visit his wards and to give demonstrations

Liverpool Annual Medical Service

This service will be held at St Luke's Church on Sunday next, October 19th, at 3 p m The Right Rev A A David, D D Bishop of Liverpool will preach the sermon It is hoped that as many members of the profession as possible will attend, especially as this will be the first address given to medical men by Dr David since his appointment The Lord Mayor and Lady Mayoress will be present and medical men are asked to wear academic dress The offertory will be made on behalf of the Royal Medical Benevolent Fund The medical men who may be prevented from being present are hereby reminded of the objects of this Fund, which needs the generous support of all practitioners The local honorary treasurer Dr J Ernest Nevins 32 Prince's Road Liverpool will gratefully acknowledge any donations sent to him

Scotland.

Royal Medico-Chirurgical Society of Glasgow

The opening meeting of the Royal Medico-Chirurgical Society of Glasgow was held on October 3rd, when Professor Archibald Young delivered his presidential address on the limitation of surgery past and present

Professor Young, far from taking a gloomy view of the outlook aimed rather at indicating the direction in which surgery as a science might progress and the lines along which further research might be pursued most profitably In a short historical survey of the earlier surgical achievements he referred to an interesting address by Erichsen in 1886, in which the following pronouncement occurred

> That the final limits of surgery have been reached in the direction of all that is mechanical and manipulative there can be I venture to think little doubt We have thus reached in many of our most important operations the final limit to which surgery can be carried Art is final but science is illimitable We have reached finality in the mere mechanical art of surgery both as to the expansion of its limits and the precision of its practice But we are yet on the threshold of the science of surgery

While such a pronouncement, said Professor Young, made nearly forty years ago and by one of the foremost surgeons of that day could not in view of the notable advances in operative method and technique since that time, be accepted as even approximately correct it contained, nevertheless, more than a grain of truth and it emphasized the separate role and the very different outlook of surgery the purely technical art and surgery the science The field of cranial surgery was chosen to illustrate some of the victories over restraints and limitations which had rendered progress difficult if not impossible and reference was made to perhaps the greatest of such victories—namely, the discovery and elaboration of anaesthetics and the conquest of microbic infection by the introduction of antiseptic practice and technique Professor Young then outlined a few of the limitations that still hindered the advance of the science of surgery—the problems of repair of tissues the manner in which the organs function and the question of periodicity as a fundamental mode of action tumour growth, the action of x rays radium and irradiation and many other such problems He urged the necessity for combined research by all concerned Before they could hope to set aside materially the restraints and limitations that still remained they would have to try many lines of research They must adopt a generous and all-embracing system of collaborative research by which the experience enthusiasm, original thought and varying points of view of many workers no only in pure surgery but also in all the allied sciences, might have cumulative weight

Housing in Scotland

The Scottish Board of Health has issued a scheme to local authorities on the Housing (Financial Provisions) Act, 1924 This Act provides for a programme extending over a period of fifteen years and aims at a production in that time of approximately 2 500 000 houses in Great Britain The amount of the increased contribution from the Exchequer to help local authorities in their building schemes under the new Act will be £9 a year for forty years in urban areas, and £12 10s a year in rural areas.

For the assistance of local authorities the Scottish Board is preparing model plans, specifications, and schedules conforming with the requirements of the Act, and embodying numerous economies that have been shown to be practicable as the result of the Board's experience in the past five years Copies of these plans, etc, are obtainable from H M Stationery Office, 120, George Street, Edinburgh It is open to local authorities not only to engage in building schemes themselves, but to assist private enterprise in the provision of houses subject to certain special conditions The type of house to which the subsidy applies varies to some extent, and the scheme includes two-storied cottages, bungalows, or houses built in flats or tenements Certain limits of area are fixed—for example, a two-storied cottage must show a minimum area of 620 square feet and a maximum of 950 The houses must be constructed in a satisfactory manner, and must possess an estimated life of not less than sixty years Although considerable latitude is allowed in the design of the house, the Board points out that the following accommodation can well be provided within the limits specified—that is, a living room of 180 square feet, and three bedrooms of 150 feet, 110 feet, and 80 feet respectively Where a parlour is provided some reduction in the size of the living room may be permitted One very proper and necessary condition needed to render a house eligible for the subsidy is that it must be provided with a bathroom containing a fixed bath

Steel Houses in Scotland

Steel houses were first brought to public notice when the Housing Bill came before the House of Lords last July The matter rose in Lord Wen's speech dealing with the bill, in which he outlined the proposal for the building of 500,000 steel houses in the next five years for the rehousing of our slum population The Committee of Inquiry, recently established by Mr Wheatley, Minister of Health, to examine new processes of house construction, last week paid a visit to Glasgow for the purpose of inspecting various types of specimen houses which have been constructed in the area In particular, the Committee visited the works of Messrs G and J Wen, where they inspected sections for one of the new steel houses A concrete foundation had been laid down outside the workshop, and this was examined A short time afterwards, on returning to the position where the foundation had been inspected, the house was found almost complete, the walls having been put up, the floor laid and covered, and the roofing almost finished while the members of the Committee were visiting another part of the works This house is of the bungalow type, containing living room and three bedrooms conforming in size to the demand of the Scottish Board of Health, also a larder coal cellar, bath room, and scullery The outer walls consist of steel plates bolted together Standard timber units for the frame and joists eliminate the necessity for the employment of a joiner, the inner walls being formed of asbestos composition do away with the necessity for plastering, and the roof being formed of metallic shingles or asbestos slates eliminates the necessity for employing a slater Further, the water pipes are made of standard lengths of copper piping with screw junctions so that the skilled plumber is to a large extent also eliminated from the construction All this standardization makes for great rapidity in construction and diminution in cost The house in question is produced for a price at the works of £360, but as larger numbers are constructed this cost will in all probability be considerably reduced Taking into account the cost of delivery and erection the total cost of the house may be taken meantime as about £450, which is a very considerable saving in comparison with houses built of brick or stone The life of the house is said to be at least fifty years and the Scottish Board of Health has already approved of the trial construction of a number of such houses by the Dundee Corporation With regard to habitability and amenity, the provision of an air cavity between the two layers of wall ensures efficient insulation against extremes of temperature, and any fear which local authorities may have with regard to monotony in the appearance of a great number of such standard houses can be dispelled by judicious planning of the site and lay out, painting of the exterior and variation of surroundings Several individuals and companies are taking an interest in the production of these houses including Messrs William Beardmore and Co, Dalmuir, on behalf of the Duke of Atholl, the Glasgow Steel Roofing Company and Messrs John MacDonald, Glasgow, and plans of two types and two sizes of houses have so far been provided One of these houses, produced by Messrs Beardmore is to be exhibited at the forthcoming Domestic Welfare Exhibition, to be held in the Kelvin Hall, Glasgow

St Andrews Institute for Clinical Research

At the opening of the winter session at the St Andrews Institute for Clinical Research Dr Maitland Ramsay delivered his inaugural address as director there was a large attendance of practitioners from Fife and from Dundee Dr Ramsay, referring to the founder of the institute, Sir James Mackenzie, expressed gratification that his name was still associated with it as president He then discussed the general principles of clinical research, as enunciated by Sir James Mackenzie He particularly emphasized the importance of clinical observation, and commented on the tendency to neglect this primary function of clinical medicine and to rely upon laboratory reports in its stead While these were of great value, they could never replace that accurate observation and weighing of clinical symptoms upon which the older physicians relied The value of the sensations experienced by the patient was often underestimated, but, speaking as a clinical ophthalmologist, he assured his audience that these were of the utmost diagnostic and prognostic significance in diseased conditions of the eye He then drew a close parallel between the symptoms of eye-strain and the sensations and disabilities experienced by patients suffering from cardiac inadequacy In conclusion, he hoped that his audience would take full advantage of the facilities of the institute for recording their observations Dr C E Douglas of Cupar, the secretary of the Fife Medical Association, congratulated Dr Ramsay on his address, and expressed his conviction that the work done at the institute was of great practical value to the practitioner He urged his audience, by their co-operation, to ensure the continued success of the institute

The winter session is being devoted to the study of renal efficiency On October 14th Professor D Waterston gave the first of two papers on the anatomy and embryology of the kidney, the second will be read on October 21st On October 28th and November 4th Professor P T Herring will deal with the physiology of the kidney, the subjects of subsequent discussions will be announced later All practitioners are cordially invited to these meetings

Correspondence.

MEDICAL SCIENCE AND GENERAL PRACTICE

Sir,—The Croydon Medical Society, a small society which has a social as well as a scientific side, has arranged a scheme of monthly meetings during the coming winter which may interest similar societies elsewhere

A series of lectures on recent advances in their own subjects will be given by recognized leaders in the scientific world of medicine In this way, it is hoped, direct contact will be established between the laboratory on the one hand and the practical clinical worker on the other

I think it will be admitted by all that the lack of liaison between the research worker and teacher of medicine or surgery at the present day is lamentable By the methods now in vogue it takes several years for a knowledge of important physiological facts to filter through even to the bulk of consultants or teachers, and probably at least twenty years before the general public receives the advantage of this knowledge in the form of approved methods of diagnosis and treatment

Dr E H Starling, Fullerton Professor of Physiology, opened the session with a paper on 'Compensation and decompensation of the heart" Reference to the study of a heart-lung preparation was made, and many practical inferences of the utmost value to practitioners present were drawn Other subjects arranged by the society include pharmacology, applied anatomy, and pathology

It is felt that infinitely more help is given to the doctor in his work by going back to the fundamentals, rather than by building up a superficial knowledge of minute details of treatment which change as continuously as all fashions do —I am, etc,

Ernest Cowell

Croydon, Oct 14th

OBSTETRICS AND LOCAL HEALTH AUTHORITIES

SIR,—Dr Louise McIlroy's letter (October 4th, p 642) is most opportune, coming at the time when the method of administration by public health authorities of obstetric work are rather rapidly crystallizing to a standard for the country at large With nearly all her letter and valuable suggestions I agree The regulation specifying the duty of a midwife when abnormality occurs in her practice, in which the words "registered medical practitioner" occur, is having an effect now which its framers never foresaw, and in my experience, even in discussions with medical officers of health, is to ways and means of carrying out their supervising work over midwives it has been used as an argument that, in any given case which might at the moment be under consideration, everything has been done quite correctly because the registered medical practitioner" had been summoned

One difficulty that one foresees in these matters is that medical officers of health are not usually expert obstetricians Who can expect them to be so? Taking the country through as a whole, it is doubtful if as yet they are as a body interested or sympathetic in this work, which is new to many of them Consequently one hesitates to endorse the suggestion that the obstetrician called in should have his report (which he should of course make) open to the *professional* criticism of the chief administrative officer

I venture to say that the difficulties mentioned by your correspondent—and they are undoubtedly very real and pressing—will be best met by her four separate suggested remedies, only excepting the expression in No 2— whole time officers"—for it is doubtful in the present state of national finance and with the present attitude of local government bodies to salaries, especially those of medical women in particular, to expect adequate pay to so skilled a practitioner who might be seldom required without overloading him or her with other duties Therefore I suggest it would be best to say in that connexion part-time officers"

With regard to the other suggestions (3) and (4) I believe these would be best brought about through central administrative action, possibly by the Ministry of Health making for instance maternity benefit *conditional on the patient* with serious complications accepting the best skilled assistance offered by the local authorities In carrying out many of these reforms I think we have here a good opportunity for work by the local medical advisory committees suggested and recommended by the British Medical Association *to be formed in all districts*—I am, etc,

Norwich Oct 10th ARTHUR CROOK

SIR,—Professor Louise McIlroy's letter is very opportune and all who have given this subject any thought will warmly endorse the sound common sense it contains Antenatal care is now a proved enormous benefit to the whole community, mothers and infants may truly eat of "the tree of life" Expert attention and advice are there for the asking of any and every expectant mother

When the labour is due—either a normal one, or premature induction, or Caesarean section, as the case may be—except for the relatively few who can be admitted to hospital the patient receives any help that happens to be available Up to this point she has been, as it were, under the eye of the medical officer of health—indirectly, it is true At what may prove to be the most critical time in the history of the case there now comes a *most illogical* hiatus Unless admitted to hospital she is "anybody's case" Should so serious a contingency as puerperal septicaemia arise, the patient is legally due to come once more under the eye of the medical officer of health The vast majority do not, for it is doubtful if any septic cases are notified unless the patient is *in extremis* and the final certification looms near and becomes more than a possibility *This is where the* supposed supervision by the medical officer of health of puerperal sepsis becomes a mere farce, and, indeed, can be nothing else so long as this state of affairs prevails It would appear that the situation is made illogical by the hiatus *mentioned above* and which is implied, if it is *not* specifically stated in Professor McIlroy's letter

To be consistent, the health authorities ought either to leave alone ante natal care and puerperal sepsis and let the whole matter of maternity be organized by some separate body, or frankly accept the whole responsibility from the beginning of pregnancy to the complete convalescence of the mother and the proved well being of the infant Professor McIlroy's suggestion of appointing expert obstetricians (if need be to act under the medical officer of health), who would undertake personally to supervise the antenatal stage attend at the labour if necessary, *and pilot the patient to complete convalescence, is the only* rational solution if the medical officer of health is to retain any interest in this work The medical officer of health *cannot* be expected to be an expert obstetrician in addition to his other already multitudinous duties but the obstetric officer appointed could be responsible to him Maternity welfare would then be a continuous and consistent pursuit, and the promise already held out by antenatal care would yield its fullest and richest fruit—I am, etc,

Harrogate Oct 10th W OSBORNE GREENWOOD, M D, B S F R S Edin

SIR,—Generally speaking, I do not believe that there is nowadays much of the unskilful or impatient midwifery practised which is condemned in Dr Louise McIlroy's letter of October 4th (p 642) In all the larger towns, and in many of the smaller ones, I think it is recognized that anything really difficult in midwifery is best sent into a hospital, and that this occurs except where manipulative or operative manœuvres are of the simplest In the country, of course removal might be impossible, but here again I do not see how an arrangement could be made workable for a doctor or specialist standing to attend wherever required

I also fail to see why a doctor called in by the midwife should be required to furnish a detailed report of his treatment to anybody In an age when we are inundated with official forms and regulations do not let us be required to add to this still another, which in most cases would be perfectly useless

As regard criticism by the medical officer of health (excellent fellow as he usually is) why should he criticize when he has no special qualification to do so and has in fact usually less knowledge of midwifery than his colleague Either he must add a special study of midwifery to his already extensive curriculum, or else the job must be taken out of his hands altogether

With regard to Dr McIlroy's numbered suggestions I would say

1 More medical inspectors would be needed than would be economically possible and more time would be lost by delay in urgent cases than would be saved otherwise Is it natural for the good general practitioner to be satisfied to be called in only if someone else cannot be procured in time?

2 Is the mother to be diagooned by these whole time officers or has she to have a say in the arrangement of her own confinement?

3 The same applies here If a woman requires help she should have the option of pleasing herself who is called in She usually forms a good idea during the years who is able to deal satisfactorily with difficulties in labour Again who will decide who is a reliable obstetrician Shall he be academical brilliant or will it be necessary for us all to submit to a practical examination?

4 In most cases we have this ready help in the hospital

I think all will agree that except in rare cases there is no place for expert and dangerous manœuvres to be undertaken at all and that these cases are best rushed off to hospital Where the cases are very urgent or naturally could hospital Where the cases are very urgent or naturally could not get the special help of whole time officers so that we are left only with those cases which are found in rural districts *with* hospitals far away, and specialists far away also

My plea would be not for a host of new officials we have too many already, and the financial burden is too great in these hard times The solution is in my opinion, much simpler and less costly, and that is a greater appreciation of the maternity hospitals already existent and a more rapid

and methodical means of transport thereto I think the *much maligned general practitioner* is not so black as he is painted, *nor are his failures so great* as we are given to suppose —I am, etc,

Hyde, Cheshire, Oct 7th J G Bennett, *M C*, M D

CELLULOSE ACETATE

Sir,—I am interested in the letters which appeared in *your issue of October 4th* relating to my "case of poisoning by cellulose acetate" By way of *reply I will give some* details which will make matters quite clear as to how the cellulose acetate solution came to be used for the making of the encasing splint

In the *Lancet* of June 14th Dr Fernandez published a communication entitled "The use of non-inflammable cellulose splints," and *proceeded to say*, "Cellulose acetate was suggested to me by the employment of cellulose dopes or varnish for aeroplane fabrics" He used "two solutions Solution 26, which is thicker and more viscous, and the thinner Solution 25 for the additional coating" Then followed the technique to be employed

In ordering these solutions Dr Fernandez's article was drawn attention to, and a quotation asked for his Nos 25 and 26 solutions The reply stated "We beg leave to *quote you for cellulose acetate solutions Nos 25 and 26*", and they were supplied in due course *There is therefore* no doubt that the preparations used were as advised by Dr Fernandez

The results were recorded by me in *your issue of* September 13th We afterwards examined the bulk of the solutions which still remain in the tins The *atmosphere* of the room felt close, and we *appreciated the presence of* a heavy odour On smelling the liquid for a few minutes we were conscious of inhaling a rather sickly vapour, which *did not invite a continued inhalation*

Acetone was clearly present, as proved at the patient's bedside If tetrachlorethane were not present, then it is obvious that an enhanced gravamen against the "solution of cellulose acetate" exists

I have, of course, no animus against this preparation in any way, but after the anxious experience we went through, when the issue of the child's life was in the balance, both my colleague and myself felt that it was only right and fair that the case should be recorded, and there the *matter rests, so far as I am concerned*

I may *add* that the patient was no weakling, but a bonny, plump little girl living an open-air life, and now again *actively getting about on crutches with* almost fully restored movements in a slightly tuberculous knee —I am, etc,

Sheffield, Oct 6th Godfrey Carter

X-RAY EXAMINATION IN RELATION TO PULMONARY TUBERCULOSIS

Sir,—It was heart-breaking to read the article in your issue of October 4th (p 615) entitled "X-Ray examination in relation to some aspects of pulmonary tuberculosis," by Dr J H Mather He writes

'Reference to some of the cases detailed below make it clear at once that *an x-ray examination may be of such supreme value* that a radiologist's report should be obtained whenever there is a shadow or doubt as to the presence of tubercle I shall endeavour to prove that this is essential in cases *where the evidence gleaned* from the physical examination of the chest is not sufficient to account for the symptoms

Again

"Now *in the three cases above quoted* there was no evidence to suggest the presence of emphysema and certainly the lesions were not small in extent we must therefore look *for some other cause* to account for the failure to detect these cases clinically I would suggest that this failure to diagnose cases of symmetrical disease is due to *the lack of a basis for comparison between the two lungs*'

The writer is generous I suggest, Sir, that the failure was due to ignorance and to a lack of appreciation of the very elements and first essentials in the diagnosis of phthisis The very first things to do are those which in the quoted cases were apparently *not done—namely*, to look for tubercle bacilli, toxaemia, and *raised temperature* These are the important things, not physical signs There may be severe active disease with no physical signs, and conversely all the physical signs of *pulmonary tuberculosis may be caused by a non-tuberculous lesion*

In the cases quoted tubercle bacilli were *found* in the sputum after the *x-ray* report had been made, and in several cases the unfortunate patients died within a few weeks

In Case I the *symptoms* were marked loss of weight, slight cough and expectoration, later emaciation, the diagnosis suggested was duodenal ulcer In Case II the symptoms were shortness of breath following influenza, husky voice, loss of weight, slight cough and expectoration, the diagnosis was aneurysm, new growth, or tuberculosis In Case III the symptoms were cough, expectoration, pain in chest, and shortness of breath, the diagnosis was gastritis

It is inconceivable how it came about that the true diagnosis was missed Such dreadful errors will be prevented, not by radiography, but by a general knowledge and acceptance of the truth that phthisis is *to be diagnosed, not* by physical signs, *but* by *tubercle bacilli*, toxaemia, and evening rise of temperature

That there were no abnormal physical signs in the cases of gross tuberculosis quoted in this article I cannot believe, but that is another question Frequently in moribund consumptives the *chest* appears quite resonant especially to hard percussion In such a stage, however, it does not matter so much if the diagnosis is missed, except that no *precautions against the spread of infection* are taken, but in early cases of pulmonary tuberculosis, if the profession is going to continue to place reliance on physical signs as a means of diagnosis, countless tragedies will continue to happen —I am, etc,

London, W Oct 12th F G Chandler

MEDICAL OFFICERS AND CONSULTING FEES

Sir,—I note that "Tuberculosis Officer" says (October 4th, p 646) he will still continue to take private fees, but in so doing he is acting in direct contradiction *to the resolution of the Representative Body at the Bradford Meeting* Such actions are undesirable in the best interests of the profession as a whole *Unity and loyalty is the only means* of strength in an Association such as ours —I am, etc,

Chichester, Oct 4th Arthur M Barford

Sir,—*To my mind one* of the chief advantages of a whole-time appointment is freedom from the distraction of wondering whether a fee should be expected or not I have had *ten years' experience* of general practice and twelve years of tuberculosis work, and I am convinced that it is better for a whole-time official to be paid an adequate salary rather *than receive a smaller salary* and be expected to supplement it by securing fees when and where he sees the opportunity Being able to advise and assist free of expense to one's *patients is a constant source* of real pleasure and satisfaction Why should tuberculosis officers give this up?

The whole-time official cannot expect to receive the same income as a successful general practitioner, but, on the other hand, he is free *from* the worry of collecting his fees and having to get money out of sick people who can hardly afford to pay him I think tuberculosis officers should stick to the substance and leave the shadow alone —I am, etc,

Folkestone, Oct 6th T M Prince

ASSISTANTS IN GENERAL PRACTICE

Sir,—I was pleased to read "Ex-Assistant's" letter in the Journal of October 11th (p 690), and I write to express agreement He mentioned £350 per annum as the average remuneration offered to assistants This, I think, *is above* the figure offered by most practitioners

Surely £250 per annum is quite an inadequate salary for an indoor assistant, and yet it is offered, even in your advertisement columns, by those practitioners *who are taking advantage of the present "glut on the market"*

I note that the British Medical Association refuses all advertisements of Public Health appointments which do not offer a certain *minimum* salary Could assistant-hops not be brought under a somewhat similar supervision, and advertisements be only accepted with the *proviso* that a minimum salary *of, say*, £300 must be offered for an indoor assistant?—I am, etc,

H W B

October 11th

SIR,—A general practitioner of some standing recently offered a medical woman, for an indoor assistantship with no exceptional advantages, a salary no more than one-seventh of that quoted by your correspondent (£350). On further inquiry, he stated that he required a woman assistant, as he knew he could not get a man so cheaply.

Medical women have no desire to undercut their professional brethren. Cannot something be done to prevent the offer of these preposterous salaries?—I am, etc.,

October 13th MEDICAL WOMAN.

THE HOURS OF MEDICAL WORK

SIR,—I must press doctors to follow Dr. Machlachlan's advice (p. 542), and will state my experience, etc. For nearly twenty-five years I have stated my hours, *x* to *y*, impressed upon patients the need to be present at *x*. If they crowd the place out near *y*, closing time, I refuse to examine them and make them come next *x*, when I have time, *y* means closing at that time, and no worker will start a new job at five minutes to his closing time. The patient who comes in at the finish, wishing to catch me when I am quiet, I remind that I have quite finished and that he will find a quiet time during the next *x* to *y* hours, also that he has missed the quiet times I had to spare. Accidents and emergencies excepted, I carry this out very strictly. If my hours do not suit them they can go to another doctor, I tell them, but it is surprising how often they see the reasonableness of it. I remind them, too, that visits after 8 p.m., *light or dark*, are night visits, and must really be necessary, as it does not pay to keep an assistant for such visits. I must confess that I have had more difficulty since daylight saving, as people do not realize that I start just as early as ever. Special cases for examination I will arrange for before *x*, but not after *y*. After *y* I have cases to read up, correspondence, next day's work to arrange.—I am, etc.,

September 21st. MEDICUS.

CARBON MONOXIDE POISONING

SIR,—Dr. R. Cunningham Affleck (October 11th, p. 690) has not brought forward any evidence which proves that his patients suffered from carbon monoxide poisoning. They might have been, and probably were, suffering from confinement in heated, stagnant air at head level with cold floor. The fact that he attributes to carbon monoxide poisoning the sudden sensation of an iron band being tightened round his forehead, felt on entering a bedroom warmed by a coke stove, shows that he is unaware of the fact that carbon monoxide only poisons by deprivation of oxygen, and that it takes time to saturate the blood up to the partial pressure of the gas present in the room. The iron band feeling can only have been caused by the effect of the heated air containing sulphur acids, and possibly other irritant fumes, on the mucous membrane of the nasal sinuses.

Mr. T. Angus and I have recently made some observations on mice exposed to the fumes of flueless gas stoves in a small room with door and window closed, which show that natural ventilation, due to difference of temperature inside and outside the room, taking place through chink and cranny, is sufficient to prevent any appreciable formation of carbon monoxide in the blood. At the same time we found that the heated air at head level was objectionable and therefore ample ventilation by open window is required when such a stove is used.—I am, etc.,

Loughton, Oct. 14th. LEONARD HILL.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

Dissolution of Parliament.

PARLIAMENT was prorogued and dissolved on October 9th after a Government defeat on October 8th. The general election is fixed for October 29th. The Ministry continues in office but all bills introduced this year to which the Royal assent had not been given by October 9th are dead. The Therapeutic Substances Bill had been dropped previously.

Vaccination.—On October 8th the Minister of Health, Mr. Wheatley, in answering Mr. F. Simon, said he would not reconsider his action in rescinding the Vaccination Order of 1923. He declined to admit that he was acting contrary to the advice of the chief medical officer of the Ministry of Health.

Lunacy Act.—In answer to Mr. J. Pickard on Mr. Wheatley said on October 8th that in the opinion of the Board of Control there were serious objections to the posting of Section 79 of the Lunacy Act in the waiting rooms of public asylums. The revised rules of the Commissioners of the Board of Control which were now awaiting statutory approval provided that on the admission of every pauper lunatic to an institution a notice should be sent to all persons whose names had been particularized as those of relatives or friends. In such notice the substance of Section 79 should be incorporated. He was not aware of any case during 1923 in which a private mental patient who had not been seen by a magistrate had been deprived of the subsequent notice of right of appeal to a magistrate through the negligence of the managers of the institution in which he was received. Mr. Wheatley added that he was not aware of any instances during the last ten years in which a penalty for detention of a sane patient had been enforced. He could not, he said in answer to a further question, undertake to introduce legislation for the alteration of the grant of £5 a head to boards of guardians for the maintenance of pauper lunatics.

Silicosis.—On October 8th the Home Secretary said he hoped to arrange for the commencement at an early date of an inquiry involving the medical examination of a number of workers in the pottery industry. Such an inquiry was required before a claim under the Workmen's Compensation (Silicosis) Acts could be brought up for pottery workers.

Tuberculosis (Ex-Service Men).—On October 9th Mr. Peel, Minister of Pensions, in answer to Commander Fletcher, said he was advised that it would not be in the best interests of ex-service men suffering from tuberculosis as a result of their war service to make final awards for pension on any general scale. It was his intention to secure awards for prolonged periods in all possible cases. He had considered the matter with his medical advisers.

Universities and Colleges.

UNIVERSITY OF OXFORD

CONGREGATIONS will be held for the purpose of granting graces and conferring degrees in Michaelmas term on the following days at 2.30 p.m.: Saturday, November 15th; Thursday, November 27th; Wednesday, December 17th.

UNIVERSITY OF CAMBRIDGE

THE following candidates have been approved at the examinations indicated:

D.P.H. (*both parts*).—S. F. Allison, C. C. P. Anning, Constance F. Appleton, W. H. I. Bathurst, G. B. H. Snell, L. P. Cornea, Mabel E. A. Deane, Alice M. S. Devar, H. S. Griffith, T. W. Hill, O. R. Horwood, D. J. Kahawita, H. J. R. Kirkpatrick, F. McKibbin, G. Meadow, Margaret J. Penne, Emily V. Saunders, Jacob Scott, R. Scott, E. S. Taylor, Ann W. Turnbull, J. Wyllie.

DIPLOMA IN HYGIENE (*both parts*).—†R. H. Bennetts, A. Fraser, M. Abdel Hamid Gohar, A. Y. Lamaie, †A. S. Muhammad, M. Aziz Yousry.

Distinguished in the application of Sanitary Science.
† Distinguished in the Principles of Hygiene.
Distinguished in Bacteriology.

UNIVERSITY OF LONDON

DEPARTMENTAL COMMITTEE ON UNIVERSITY COMMISSIONS' REPORT.

The President of the Board of Education has appointed the following to be a Departmental Committee to consider the final report of the Royal Commission on University Education in London, dated March 27th, 1913, and having regard to present circumstances and after consultation with the persons and bodies concerned to indicate what are the principal changes now most needed in the existing constitution of the University of London and on what basis a Statutory Commission should be set up to frame new statutes for the University: Lord Ernle (chairman), Sir Robert Blair, Mr. H. L. Eason, C.B., C.M.G. (Medical Superintendent of Guy's Hospital), Mr. H. L. Lees Smith, Sir Henry Miers, F.R.S., Professor A. F. Pollard, Sir Ambrose Heath, Sir Bertram Blount, K.C.B., Miss K. Wallas, and Mr. S. H. Wood, as secretary to Sir Robert Blair. Mr. H. L. Eason, C.B., C.M.G. (Medical Superintendent of Guy's Hospital), Mr. H. L. Lees Smith, Sir Henry Miers, F.R.S., Professor A. F. Pollard, Sir Ambrose Heath, Sir Bertram Blount, K.C.B., Miss K. Wallas, and Mr. S. H. Wood as secretary to the Board of Education, King Charles Street, Whitehall, S.W.1.

At an extraordinary meeting of the Senate, held on October 9th, when the Vice-Chancellor, Professor E. A. Gardner, L.H.D., was in the chair, a communication was considered, dated September 15th, 1924, from the President of the Board of Education, in reference to the appointment of a Departmental Committee to matters connected with the University, the following resolution was unanimously carried:

That the President of the Board of Education be requested to remind that the Senate was not consulted as to the reference to the Haldane Committee on, nor represented upon, nor gave evidence before, and that, having regard to the successful progress of the University since the report of the Commission, the Senate is of opinion that such changes in the organization of the University as may be necessary can be more readily effected by amendments promoted by the University than by a Statutory revision of the Letters Patent as contemplated by the Act of 1923, but that the Senate will be prepared to

furnish through its officers and appropriate committees any information desired by the Departmental Committee, and trusts that the various bodies and interests represented on the Senate will receive a full opportunity of putting individually or collectively before the Departmental Committee their views on the matters under consideration

UNIVERSITY OF SHEFFIELD

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A QUARTERLY council meeting was held on October 9th, when the President, Sir John Bland Sutton, was in the chair

Annual Report

The annual report to be presented to the Fellows and Members at the annual meeting on Thursday, November 20th, was approved and adopted It contains a record of the work of the College in its various departments from August 1st, 1923, to July 31st, 1924 In addition to an account of the annual meeting in November 1923, and a note of the lectures and awards during the year, the report contains a detailed statement of the work of reorganizing the museum under the supervision of Professor Shattock until his death The work in connexion with the army *medical collection* has made good progress and the specimens, numbering nearly 2,500, are being arranged in groups illustrative of different conditions The teratological collection has been rearranged and extended during the year, and the new descriptive catalogue of the collection of surgical instruments in the museum has been completed by the addition of a final volume devoted to the series of instruments in use among barbarians and semi-civilized nations The department of osteology has received important additions during the year by gifts of great value of human remains from the excavations at Scarborough, Chester and elsewhere The financial part of the report shows that the gross income of the College, exclusive of income from the trust funds, amounts to £46 211, being £3 244 more than in the previous year The gross receipts from the Conjoint Examination Board are £4,360 higher, mainly due to an increase in the examination and diploma fees for the Membership The total expenditure in respect of revenue amounts to £37 747 and is £343 less than the expenditure of the previous year The balance on the revenue is £8 464 a larger sum than has been realized in any previous year In the coming year it is proposed to carry out considerable repairs and alterations in the College buildings at an estimated cost of not less than £2 500 During the period under review 750 diplomas of Membership were issued (including 122 to women) and 50 persons (including 3 women) were admitted to the Fellowship, the licence in dental surgery was granted to 266 persons, including 12 women

Jenks Scholarship

Mr Anthony Richard Charles Higham, formerly a student at Epsom College, was nominated as the thirty second Jenks Scholar

Gilbert Blane Medal

A "Sir Gilbert Blane" medal has been awarded to Surgeon Lieutenant Commander Harold Boultbee Padwick, D S O, B A Promotion Examination, 1924

Lectures

The Bradshaw Lecture on "Some Clinical Aspects of Carcinoma of the Breast" will be delivered by Mr Raymond Johnson on Thursday, November 6th, at 5 o'clock, and the Thomas Vicary Lecture on "Sir Richard Owen as Conservator" will be delivered by Sir Arthur Keith on Wednesday, November 12th, at 5 o'clock

Obituary.

FREDERICK DEIGHTON, M A, M B CANTAB,

Consulting Surgeon, Addenbrooke's Hospital, Cambridge

MR FREDERICK DEIGHTON, consulting surgeon to Addenbrooke's Hospital, died at his residence in Cambridge on September 29th, at the age of 70 He held a high position in the university town, both as an able surgeon and as a much esteemed townsman He was born in Cambridge where his father was in practice as a surgeon, and, save for his student years at hospital, spent the whole of his life in the town Yet of few men can it be said more accurately that there was no provincialism or stagnation in his work He constantly sought out the new and brought it into line with his practice

Educated privately, he went to St Peter's College, Cambridge, where he began as a mathematician, but later took up natural science, in which he took his degree From Cambridge he went to St George's Hospital It was whilst holding the post of assistant surgical registrar that he was called back to Cambridge to take over his father's practice owing to his sudden death in an accident This was in 1883, when he had taken the M R C S Eng Compelled by circumstances to abandon all idea of work in London, Mr Deighton made up his mind to succeed in his native town With the responsibilities of practice on his shoulders he gave time to work at Addenbrooke's Hospital, and worked for and took the M A and M B at Cambridge University His ability and industry were recognized when, in 1891, at the first vacancy, he was appointed assistant surgeon at Addenbrooke's This began a long association with the hospital, covering a period of twenty-six years and only ending on his retirement in 1919 During this time his versatility was shown in the special work he did in addition to that of general surgeon For several years he had the anal and gynæcological departments in his charge, both of which owed their inception to him With these departments he kept abreast of the times, frequently going away to see the work of other men and the best and most modern ways of treating disease Yet, at the same time, he was a very deliberate thinker, not to be easily moved, and only taking on new methods where his own experience confirmed that of others In operating there was no show of brilliancy, but meticulous care and delicate manipulation, so that haemorrhage and shock were reduced to a minimum One of his house surgeons, talking gratefully of his former chief, ten years after leaving Addenbrooke's, stated that, in his experience, he had never met a better operator for *thyroidectomy* This man's experience had been wide and varied, and included reading for the F R C S Eng It was a great tribute, but thoroughly deserved

Mr Deighton's knowledge of surgery and his judgement were equally good He could trace the evolution of an operation and explain its virtues and its drawbacks, and could give a wide, comprehensive view of surgery which was invaluable to those brought in contact with him Again, there was no improvement in aseptic technique that he did not master and assimilate, and right up to his retirement from hospital he was as much up to date as the youngest of his colleagues But his most careful work as a surgeon was combined with a kindliness and *cheeriness of disposition*, a thorough friendliness of manner, which made him friends with all who worked with him Though he could speak plainly and to the point where the welfare of his patients required it, he was absolutely devoid of any sternness or severity, and increasing acquaintance added to the respect and regard one had for him He was devoid of all pretentiousness, and honest and sincere in his outlook on everything

During the war he was lieutenant-colonel in the R A M C (T), serving at the 1st Eastern General Hospital, and for some two years he was also surgeon to the Officers' (Research) Hospital Two of his sons lost their lives in the war, one of them belonging to his father's profession

Mr Deighton was president of the Cambridge Medical Society for the years 1902 and 1903, and his main contributions were to that society He was also ex-president

of the Cambridge and Huntingdon Branch of the British Medical Association His advice on all matters affecting the profession was listened to with interest as being a well balanced and sound opinion, and time showed that his outlook on medical politics was worth seeking When at Peterhouse he played cricket for his college, and in his early days of practice, when limited time meant intensive play, he took up real tennis In the nineties he became an expert chess player, twice playing for the South against the North At the age of 55 he took to golf, and his keenness and natural skill are evidenced by his handicap being down to six at the age of 60 He retained his keenness in the game until the end, and even when bed ridden was intensely interested to hear of the results of other people's play

He leaves a widow (daughter of the late Mr Francis Fisher, Crown Solicitor, Sydney, N S W), three daughters and two sons, one of whom is in the medical profession

W H B

Medical News.

A SERIES of museum demonstrations on anatomy and malformation of the heart will be given in the theatre of the Royal College of Surgeons of England Lincoln s Inn Fields W C by Sir Arthur Keith, F R S on Fridays, October 17th 24th and 31st, at 5 p m The first demonstration will deal with specimens illustrating the evolution of the human heart the second on common kinds of congenital malformation, and the third on applied anatomy of the heart

ACCORDING to recent statistics the total French losses in the war amounted to 1 325 000 dead and missing Of these 674,700 were killed in battle 250 000 died of wounds 175 000 of diseases and 225,000 were missing 9,287 822 were admitted to hospital of whom 3 594 889 were wounded and 5 988 213 were suffering from various diseases The proportion of killed and wounded was 1 in 4 About one fifth of the wounded had more than one wound After 1916 about 80 per cent of the wounded could be sent back to the front

THE next meetings of the Royal Commission on Lunacy and Mental Disorder will be held at the Royal Commissions House 5 Old Palace Yard on Tuesday and Wednesday October 21st and 22nd, beginning at 10 30 a m each day

OWING to the recent builders strike the consecration of the memorial chapel of Epsom College has been postponed from November 1st to Saturday February 21st 1925 The ceremony will be conducted by the Bishop of Winchester

THE fourth of the series of post graduate lectures on cancer will be given by Sir StClair Thomson on "Cancer of the larynx" on October 20th in the West Lecture Hall of the Royal Society of Medicine at 5 30 p m At St Peter s Hospital a four weeks special course in urology will begin on October 20th A fortnight s intensive course in cardiology at the National Hospital for Diseases of the Heart commences also on October 20th The Hampstead General Hospital has arranged a two weeks intensive course, embracing all the general and special departments of medicine and surgery, from October 27th to November 7th The following hospitals will participate in a combined course on children s diseases from October 27th to November 15th Paddington Green Children s Hospital, the Victoria Hospital for Children, and the Children s Clinic Courses in November are as follows dermatology, at St John s Hospital for Diseases of the Skin gynaecology, at the Chelsea Hospital for Women proctology, at St Mark s Hospital, venereal disease at the London Lock Hospital and a general course in medicine, surgery and gynaecology at the Royal Waterloo Hospital The syllabus of each of these courses can be had from the Secretary of the Fellowship of Medicine at 1, Wimpole Street, W 1

THE opening lecture of the winter session at the North East London Post Graduate College will be given on Tuesday, October 21st, at 4 30 p m , by Colonel L W Harrison, on the diagnosis and treatment of gonorrhœa in the male The lecture will be illustrated by a cinematograph film and will be open to any medical practitioners who care to attend An opportunity will be afforded from 3 30 to 4 30 p m for a visit of inspection of the new wards theatre and other recent extensions of the hospital Those wishing to attend are asked to intimate their intention to the Dean at the Prince of Wales s General Hospital, Tottenham, N 15, so that tea may be provided for them

THE Royal Society of Tropical Medicine and Hygiene will hold the opening meeting of the new session on Thursday October 23rd at 11, Chandos Street Cavendish Square After a demonstration at 7 45 p m on some malaria carrying mosquitos and their larvae, the President, Surgeon Rear Admiral Sir Percy Bassett Smith K C B , will take the chair, and a paper will be read by Sir Malcolm Watson, M D of the Malay States, entitled Observations on malaria control with special reference to the Assam Tea Gardens illustrated by lantern slides

THE next meeting of the Biochemical Society will be held at Cambridge on Saturday, October 25 h The society exists to facilitate intercourse between those biologists and chemists who are interested in the investigation of problems common to both, including animal and vegetable physiology and pathology, agriculture, and brewing Members of the society are entitled to use the library of the Chemical Society Burlington House, London, W

THE annual dinner of the West Riding Association of the Graduates of the University of Edinburgh will be held on Wednesday, November 12th, at the Midland Hotel Bradford at 7 15 p m The annual general meeting will take place at 6 30 The guest of the evening will be Professor George M Robertson, M D , Professor of Psychiatry in the University of Edinburgh

DR HENRY JELLETT late Master of the Rotunda Hospital Dublin, has been appointed consulting obstetrician to the Health Department of New Zealand

THE Home Secretary has issued an Order, which will come into force on January 1st, 1925, applying the provisions of Section 73 of the Factory and Workshop Act 1901, to all cases of poisoning by carbon bisulphide, poisoning by aniline and its compounds, and chronic benzine poisoning, occurring in a factory or workshop This section relates to the notification of certain diseases contracted in factories or workshops

MR TOM EASTHAM, K.C , M B , has been appointed Recorder of Oldham

A MEETING under the auspices of the National Council for Mental Hygiene will be held at the Liverpool Medical Institution 114 Mount Pleasant Liverpool on Friday, October 24th at 4 30 p m The speaker will be Sir Maurice Craig M D All medical practitioners are cordially invited

AT the meeting of the Tuberculosis Society, to-day (Friday, October 17th) at 8 o clock at 1 Upper Montague Street Russell Square Dr O Donovan will make a communication on cutaneous tuberculosis Members of the society are invited to the next meeting of the Society of Superintendents of Tuberculosis Institutions to be held at 122 Harley Street W 1 at 3 p m on October 20th when diet in cases of pulmonary tuberculosis and the duration of sanatorium treatment will be discussed

AT the meeting of the Medico Legal Society, to be held at 11 Chandos Street Cavendish Square W 1 on Tuesday October 21st, at 8 30 p m , Professor Harvey Littlejohn will present communications on (1) Judicial hanging—a humane method of execution and (2) What is the fatal dose of strychnine? —to be followed by a discussion

THE sixth international medical post graduate course was held in Carlsbad from September 7th to 13th Professor Ascoli of Rome read a paper on chronic malaria, and Dr Louis Fischer of New York dealt with rickets Professor Chagas of Rio de Janeiro reported a special variety of trypanosomiasis in Brazil, and Professor Katsunuma of Japan discussed the cell function of the oxydase reaction Other readers of papers were Professor Benedikt of Budapest Professor Bergmark of Upsala, Professor Schur of Vienna Professor Arnt de Berlin Professor Christiania and Professor L Asher of Berne The course attracted a large number of doctors from many countries

THE forty first exhibition of the Royal Institute of Oil Painters, now open at 195 Piccadilly contains an excellent portrait by Mr John St Helier Lander P O I of the Treasurer of the British Medical Association Mr V Bulloch Harman F P C S robed in the gown and hood of a Bachelor of Medicine of the University of Cambridge

MR BASIL GRAVES, curator of the Royal Westminster Ophthalmic Hospital and formerly research scholar of the British Medical Association, has been appointed clinical lecturer and special instructor in charge of the department for microscopy of the living eye in the Department of Ophthalmology, Graduate School of Medicine University of Pennsylvania U S A , for a period of three months from January 1st 1925

SIR HENRY DUKE (President), in the Divorce Division of the High Court of Justice on October 15 h said that the medical inspectors appointed by the court in undefended suits had resolved to give their services gratuitously in poor persons cases and by this self denying resolution they brought themselves into line with members of the Bar and solicitors

AT the September matriculation examination of the University of London 35 candidates passed in the first division and 343 in the second division In addition 22 took the supplementary certificate in Latin

DR A J CRONIN of Tredegar, Mon, has been appointed a temporary medical inspector under the Coal Mines Act, 1911

DR JEAN GUISEZ of Paris has been invited by the University of London to give a lecture at the house of the Royal Society of Medicine, 1, Wimpole Street, W, on November 6th, at 5 p m, on malignant disease of the oesophagus

The Final Report of the Departmental Committee on the Use of Preservatives and Colouring Matters in Food has now been presented to the Minister of Health and will shortly be published The terms of reference having been extended to include the treatment of flour with chemical substances, the Committee will now proceed to inquire into this question, and communications on the subject should be addressed to the secretary, Mr A M Legge, of the Ministry of Health, Whitehall, S W 1

IN connexion with the diamond jubilee of the Guild of St Luke arrangements have been made for a luncheon to be held on October 18th at Pagani's Restaurant, 42, Great Portland Street, W The Rev Canon Arnott, F R C S, the surviving founder of the Guild, is expected to be present On Tuesday, October 21st, the musical portion of the festival service in St Paul's Cathedral will be rendered by the combined choirs of St Mary the Virgin, Primrose Hill, and the League of Artists, under the direction of Mr Geoffrey Shaw The November Chapter of the Guild will be held on November 13th, at 5 p m, at King's College, Strand, when the Rev T H Passmore will read a paper The chapter on December 9th will be addressed by the Rev E P Lewis, D D

AT the closing session of the Ceylon Legislative Council on August 28th last, the Governor, Sir William Manning, said that the medical department of the colony had expanded very considerably during the last three years In 1921 the expenditure was Rs 5,093,689, in 1924 it has been Rs 7,448,600 In 1921 the expenditure on medical research was Rs 600, to day it is Rs 70,142 In this period 1,500,000 persons have been treated for ankylostomiasis For the treatment of parangi, nine whole time medical officers are employed—one in each province, ten new hospitals and thirty three new dispensaries have been opened, and additions and improvements to forty hospitals have been made A malariologist has been appointed, with a staff to assist him Sanitation has been seriously taken up, and four medical officers of health and sixty five sanitary inspectors appointed For estate medical inspection six whole time officers have been appointed The department has shared in the general development which has taken place during the period 1921-24 According to the Governor, Ceylon is better supplied with hospitals and dispensaries than any other tropical colony

QUERIES AND ANSWERS

SPAS OF FRANCE

WE are asked to state that in consequence of the reference to the approaching publication of a volume entitled *The Spas of France* contained in the article Some Vosges Spas" published in our issue of September 20 h (p 538) the Office Français de Tourisme (56, Haymarket, London, S W 1) has received a large number of inquiries with regard to the book The translation is however not yet ready and it is not likely that the volume will be available before the beginning of next year

SENILE CRANIOTABES

"ROSACEA" asks how to treat craniotabes in an old lady of 84 years The bone has thinned like an eggshell over one parietal bone The patient takes plenty of food and green vegetable

DISCHARGE FROM THE NIPPLE

"X Y" writes A lady, aged about 55, has lately noticed a straw coloured discharge from the nipple There is nothing to be felt in the breast, but about four years ago there was removed from it by operation a growth which was pronounced to be inflammatory and non malignant What is the significance of this discharge? Does it denote early malignant change in the breast or nipple?

OBSTINATE NASAL CATARRH IN AN INFANT

"G E" asks for suggestions for the treatment of obstinate nasal catarrh in an infant of 6 months The child is otherwise perfectly well, and his parents are healthy The condition developed when the child was a few weeks old it has never been completely cured, and often becomes bad enough to interfere with sucking

INCOME TAX

Demand for Accounts

"R D A" has been asked by the local inspector of taxes for his accounts for the three years ended December 31st, 1920, but cannot comply with the request as the practice was then carried on by a deputy, since dead He asks whether he can deduct one half of the annual value of his house as an expense of the practice

*** The inspector of taxes has no legal right to require the production of accounts, but would be within his statutory functions in bringing any particular case to the notice of the Commissioners, who might make increased assessments and call for the accounts if they were appealed against by the person assessed It is obviously more convenient for all parties that any reasonable request for accounts made by the inspector should be met and the matter settled with the person concerned without the formalities and inconveniences of an appeal In this case "R D A" is in a real difficulty, and we suggest that he explain the matter to the inspector—preferably orally—and he will probably find that the matter is capable of amicable settlement With regard to the annual value deduction, he can include in the expenses a reasonable proportion, one half is, speaking generally, quite reasonable when the property includes surgery and garage

Anticipatory Deduction

"J E H S" refers to a reply to his inquiry in our issue of October 4th (p 650), and explains that the repayment in question was for 1923-24

*** The action of the inspector is not so unreasonable as would appear from the note in our previous issue, but is still open to objection in principle He cannot claim a set off against money not yet legally due from our correspondent We suggest that a protest be lodged and a supplementary repayment requested

Work under the Ministry of Pensions

"E D C" was engaged for some time on locumtenent work and sessional work for the Ministry of Pensions, but in recent years has confined his professional work to the latter He asks if he can claim the three years' average

*** The question resolves itself into this—are the earnings the profits of an employment? We have not before us full particulars of the contract of service with the Ministry, but we are of the opinion that in substance it is a contract of employment If so, "E D C" cannot claim the average and is assessable on the earnings of the actual year The arrangement under which such earnings are pooled with general practice earnings for one (average) assessment appears to be without legal justification, and to be based on a departmental concession to the convenience of the profession and, incidentally, its own officers

LETTERS NOTES ETC

OBSTETRICS AND LOCAL HEALTH AUTHORITIES

DR AGNES HILL NICOLL asks us to correct the wording of a passage in the last paragraph of her letter on this subject published in the JOURNAL of October 11th, p 688 The passage should read 'As regards nursing mothers, it will always be more natural and convenient for the mother of a young baby who attends a clinic with her baby to have supervision," etc

ACUTE EPIPHYSITIS

SIR JOHN O'CONOR K B E, M D (*Buenos Aires*), writes, with reference to the discussion on acute epiphysitis in the Surgical Section at the Annual Meeting at Bradford, to express the very strong view that radical operative treatment is necessary and that in what is commonly known as acute epiphysitis the whole infected part on of the medullary canal should be laid wide open in an endeavour to obviate pyaemia

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 37, 38, 39 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies a pages 40 and 41

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *iii*

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

284 Influenza and Meningococcal Infection

O DOPTER (*Journ de Méd de Bordeaux et du Sud Ouest*, August 25th, 1924, p 700) records a small epidemic of cerebro spinal fever which occurred in the garrison at Rochefort in December, 1923 Five cases occurred in the course of four days, then there were no more for twenty five days, when there was another case followed by the seventh a fortnight later, and by the eighth and last after another six weeks The outbreak thus consisted in the sudden appearance of an epidemic focus followed by sporadic cases, which occurred during the course of the next three months Meningococcus infection had been endemic in the garrison for some years The outbreak of cerebro spinal fever occurred during an epidemic of influenza, and as soon as the latter had subsided the meningococcus infection resumed its usual insidious course Influenza may be regarded as one of the favouring causes of meningococcal infection, and may give rise to outbreaks which are apparently primary, but are really only the expression of an exacerbation of meningococcal rhino pharyngitis Dopter refers to the investigations made in 1919 by W Fletcher, who found the meningococcus as well as *B influenzae* in the lungs and heart blood of American soldiers who had died of influenzal bronchopneumonia

285 Intestinal Toxaemia

R S BOLES (*Therap Gaz*, August, 1924 p 548) believes the poisoning of intestinal toxaemia to be due to absorption of toxins from the lower ileum and caecum in consequence of regurgitation from the colon through an incompetent ileo colic valve The substances so absorbed, he thinks, are indole containing derivatives of amino-acids due to the action of putrefactive bacteria flourishing in consequence of excessive protein ingested or producing toxic substances by attacking the amino-acids when there is insufficiency of carbohydrate in the intestine Some of the toxins identified are tyramin, which raises the blood pressure histamin and cadaverin, which lower it and indole which produces headache and vomiting It is possible that these toxins attack one kind of tissue in one person another kind in another person, thus one patient may have gastro intestinal symptoms, another articular, a third neural, a fourth mental The liver, too, may "detoxicate" more thoroughly in some persons than in others Among the general symptoms are physical and mental fatigue, dizziness, headache, cold extremities, anaemia, the gastro intestinal symptoms are anorexia or capricious appetite hyperacidity or achylia gastric atony, pyloro spasm, spastic colitis, appendicitis and cholecystitis The neural and mental symptoms may include neuritis, neurasthenia, melancholia insomnia indecision, migraine, epilepsy and dementia praecox The cutaneous manifestations include urticaria acne eczema, erythema nodosum, and erythema multiforme Boles mentions three cases of brittle nails cured by stopping the toxaemia he traces certain cases of blurred vision, scotomata iritis and choroiditis to this intestinal origin Diagnosis involves a careful analysis of symptoms and a thorough physical examination, in which x ray examination should always be employed, the faeces and urine being also examined Treatment by continuous irrigation of the colon is highly recommended, and milk cultures of *B acidophilus* appear to be beneficial agar and liquid paraffin have been found useful also

286 Luminal and Pyramidon Rashes in the same Patient

W BOTHE (*Klin Woch*, September 9th, 1924, p 1678) describes the following case A girl aged 11 who had suffered from epilepsy since the age of 5 had been treated formerly with bromides but for three weeks had received a daily dose of luminal (0 1 gram) A morbilliform rash then appeared, and in spite of treatment she developed a universal drug erythema resembling a salvarsan dermatitis with considerable fever (105 F) marked generalized oedema and painful fissures at the flexures of the joints This was followed by desquamation of the abdomen back, hands and feet No visceral lesion was detected but there was marked leucocytosis with eosinophilia (25 per cent) After nine weeks the temperature became normal, but there was total loss of hair and of nails with pyodermia After the disappearance of the dermatitis sensitization tests were carried out with a 50 per cent luminal sodium ointment and minute oral doses of the same substance (=0 01 and 0 05 gram) all tests were positive the former oral dose produced diffuse erythema, while after the latter the rash became intense and universal None of the controls reacted On recurrence of epilepsy three and a half months later, the patient was given 0 2 gram of pyramidon daily (by mouth) Two days later a scarlatiniform erythema appeared, with bullae on the hands, which healed after desquamation The sensitization tests were positive, as with luminal

287 Typhoid Bacilluria.

A HERZ and G HEPPNHEIMER (*Wien Arch f inn Med* August 15th 1924 p 413) record in detail their observations on typhoid bacilluria, based on 374 typhoid affections with 219 cases of specific bacilluria they estimate that this bacilluria occurs in about 50 per cent of the cases The most characteristic indication was pus in the urine They point out that bacilluria is always associated with disease in the urinary organs, most frequently with localized kidney disease, and with a localized interstitial infiltration (lymphoma and abscess) Other associated diseases are affections of the pelvis of the kidney, bladder, prostate and vesiculae seminales The chief causes of the permanent excretion of typhoid bacilli are stated to be chronic inflammatory processes in the pelvis of the kidneys and the bladder and also typhoid affections of the urinary organs following a non typhoid process, such as stone in the kidney and bladder, hydronephrosis, pyonephrosis abscess in the prostate and vesiculae seminales The excretion of typhoid bacilli in the urine plays an important part in the transmission of the disease, and the danger of infection in this way is greater than that of infection from the faeces As regards the prophylaxis and treatment of bacilluria, the authors recommend, in every case of typhoid or paratyphoid fever, hexamine in doses of twenty grains daily, directly the diagnosis is made and continued on several weeks during convalescence If prophylactic treatment has not been carried out, a preparation of hexamine should be given for at least four weeks when bacilluria is diagnosed If this does not free the urine from bacilli accurate examination of the urinary tract by means of the cysto-cope and ureter catheter, and functional tests of the kidneys, should be carried out the seat of the disease localized and eventually, in certain cases, operation may have to be considered.

288 The Tonsils in Rheumatic Arthritis.

OSTEN HOLSTI (*Finska Läkaresällskapets Handlingar* May June, 1924 p 365) has made microscopic examinations of a large series of tonsils taken from three classes of per sons (1) healthy persons (2) patients suffering from rheumatic arthritis, and (3) patients suffering from a variety of other diseases, such as heart disease The 13 tonsils taken from healthy persons showed signs of slight chronic inflammatory changes but no severe destructive processes About two-thirds of the 83 tonsils taken from the subjects of rheumatic arthritis (chronic rheumatic arthritis acute relapsing arthritis and acute arthritis) showed much more extensive and severe disease, necroses and far reaching changes in the vessels being demonstrable The 107 tonsils taken from patients suffering from diseases other than arthritis showed slight chronic inflammatory changes similar to those in the first group of healthy persons After a detailed study of the clinical relationship of attacks of sore throat to the arthritic disease in his patients the author comes to the conclusion that there is often a definite connexion between disease of the tonsils and of the joints

289 Early Jaundice in Syphilis.

C W BOTTEMA (*Nederl Tydschr v Geneesk* August 2nd, 1924 p 653) states that jaundice is a rare occurrence in syphilis and in recent infections usually develops after the appearance of the secondary rash In such cases it may be (1) haematogenous or haemolytic (2) hepatogenous being either intrahepatogenous or extrahepatogenous through occlusion of the bile ducts by swelling of the mucous membrane or enlarged lymphatic glands (3) caused by a combination of haematogenous and hepatogenous factors probably occurs in the majority of cases Bottema records the case of a man aged 18 who developed jaundice about the same time as the inguinal adenitis accompanying the chancre or about four weeks before the appearance of a secondary rash Rapid disappearance of the jaundice took place after anti-syphilitic treatment

Surgery.

290 Conservative Treatment of Pott's Disease

S LESKINEN (*Acta Chir Scand*, August 13th, 1924, p 193) has investigated the after histories of patients given conservative treatment for Pott's disease in a hospital in Helsingfors in the period 1895–1920 Of the 241 patients, as many as 21 died in hospital Only 137 patients could be traced, and it was found that 43 had died after leaving hospital, the mortality, therefore, was as high as 40 5 per cent The survivors who were traced were classified according as they were still ill, fairly well, or cured It was found that, apart from the mortality of 40 5 per cent, the patients who were still ill represented 12 per cent, the patients who were fairly well 17 1 per cent, and the patients who were cured 30 4 per cent of all the patients whose fate could be ascertained Tuberculosis was the cause of death in 57 of the 64 cases terminating fatally The prognosis proved to be best for caries of the cervical vertebrae, the proportion of cases of complete recovery being as high as 68 5 per cent The prognosis was worst for the cases of disease of the thoracic vertebrae, only 21 1 per cent of the patients in this class recovering completely A classification of the patients, according as their disease was or was not complicated by abscesses, fistulae, etc, showed how enormously such complications reduced the expectation of life, only 8 4 per cent of the patients with fistulae recovered completely

291 Treatment of Tuberculous Abscesses and Fistulae

G J HUET (*Nederl Tydschr v Geneesk*, June 21st, 1924, p 2826) alludes to the work of Lansberg, Kuyzer, and Sir Leonard Rogers (see JOURNAL, February 8th, 1919, p 147) on the treatment of tuberculosis and leprosy by injections of cod liver oil or sodium morrhuate, and reports his experience of injections of tuberculous abscesses and fistulae with a mixture of cod liver oil and iodoform in place of the ordinary iodoform emulsion He obtained such remarkable and rapid improvement that as he had not sufficient cases of his own he invited van Dorp Beucker Andreae to test the method in the Marine Hospital at Katwijk D VAN DORP BEUCKER ANDREAE and F S L VAN BREDO (Ibid, July 26th, 1924, p 511) have treated 31 cases of tuberculous abscesses or fistulae by injection of neutralized and sterilized cod liver oil combined with bismuth carbonate, as recommended by Kuyzer Like this observer, the authors found that this preparation penetrates farther than Beck's paste owing to its greater fluidity The results of treatment were as follows In 5 cases the disease progressed in spite of treatment, and in 3 it remained stationary All these 8 cases were in children suffering from very severe forms of tuberculosis of the knee hip, or spine, of several years' duration Some of the cases could not be taken into consideration, as they had to leave the hospital prematurely for other than medical reasons In the remaining 23 cases considerable improvement or actual recovery took place during treatment, in some cases, indeed, immediately after it had begun Although the number of cases treated was not sufficient to be conclusive, the results obtained justified further trial of the method

292 Steinach's Operation

LEVY LENZ (*Deut med Woch*, August 15th, 1924, p 1121) has ligatured the vas according to Steinach's technique in about 50 cases, and finds that the operation can be easily performed under local anaesthesia in five to ten minutes, under ambulatory conditions The vas should be secured as close to the testicle as possible, ligatured in two places with silk, and then divided The 2 cm long incision in the scrotum is sutured at once, a small dressing is applied, and a suspensory bandage worn for a fortnight The author says there may be an immediate transitory effect, but permanent results are not to be expected till four to six months later He is not very enthusiastic about this operation, and in no case of what he calls normal old age has he seen any benefits follow it, only when old age has come on early, and presents morbid rather than normal characteristics, with slight mental depression, has the operation seemed to have a favourable effect He adds that it is difficult to form an accurate estimate of its intrinsic value because of the element of suggestion, and also because some surgeons have performed this operation who scale without paying due regard to the indications for it

293 Some Faucial Anomalies

S COHEN (*Med Journ and Record*, September 3rd, 1924, p 232) describes three anomalies of the mouth and fauces (1) The styloid process may project into the tonsillar fossa and be discovered only after tonsillectomy He remarks that the styloid process varies considerably in length, but the normal length is 1 inch, if exposed by tonsillectomy it does not delay healing nor require removal (2) Arterial pulsation may be seen in proximity to the tonsil, the vessel involved being (*a*) a tortuous and aberrant internal carotid, (*b*) the common carotid trunk (when the internal carotid is absent), (*c*) the external carotid, (*d*) the ascending pharyngeal, or (*e*) the ascending palatine arteries These abnormal vessels may add greatly to the danger of tonsillectomy, the possibility of their presence requires careful preliminary examination (3) Supernumerary tongue Cohen's patient was an infant, aged 10 days Shortly after birth inspiratory dyspnoea was observed, this was relieved when the head was lowered A body was seen in the pharynx attached to the left pharyngeal wall and resembling the tongue in appearance, its pedicle was attached behind the left posterior faucial pillar When this was drawn forward the dyspnoea was relieved. The body was removed with a snare, and on histological examination was found to be structurally like the tongue

294 Cervical Sympathectomy

F J SMITH and R D MCCLURE (*Surg, Gynecol and Obstet*, August, 1924, p 210) recall that cervical sympathectomy has been performed for angina pectoris by various surgeons since 1896 Jonnesco advocates resection of the entire cervical sympathetic chain below the level of the superior cervical ganglion, including the first thoracic ganglion This operation has been performed under local anaesthesia alone or combined with gas and oxygen After the resection the characteristic enophthalmos and pupillary miosis usually develop promptly on the side of the operation, occasionally there is also transient conjunctivitis on the same side The authors point out that although unilateral or bilateral resection may greatly lessen the number and severity of the attacks, it must not be counted on to secure complete relief from pain, unless the first thoracic ganglion is included in the resection The resection should be done on the side of greatest pain first, followed by a similar operation on the other side if complete relief is not obtained The indications for operation are frequent and severe attacks up of occupation, the main contrain upend ing myocardial insufficiency The authors record in detail two cases where this treatment was carried out with definite benefit but without complete cure

Neurology and Psychology.

295 Progress in Psychiatry.

I H CORIAT (*Boston Med and Surg Journ*, September 11th, 1924, p 499), in a general review, observes that the old descriptive psychiatry of Kraepelin is being displaced rapidly by the newer interpretative psychiatry (Bleuler) which utilizes the psycho analytical principles of Freud, though Kraepelin's classification of clinical types has outlasted those of other writers Coriat regards Brill's translation of Bleuler's text book as an important advance, particularly the conception of schizophrenic negativism Coriat adds that, according to Bleuler, the predisposing causes of negativistic phenomena may be divided into (1) Ambitendency, which sets free with every tendency a counter tendency (2) Ambivalency, which gives the same idea two contrary feeling tones, investing the same thought simultaneously with both a positive and negative character (3) The schizophrenic splitting of the psyche (4) Confusion and imperfect logic of general schizophrenic thought, rendering theoretical and practical adaptation to reality difficult or impossible He quotes Bleuler as stating that in the psycho analysis of hundreds of patients of schizophrenia none was without a sexual complex, and that in the majority it was a dominant symptom Bleuler agrees with Freud's views on sublimation and repression of the sexual instinct Coriat continues by pointing out that Karl Wilmanns of Heidelberg recognizes the importance of Bleuler's work on dementia praecox, and admits that Freud has exercised a tremendous influence and has materially contributed to modern developments, though feeling that this approach has been only partially successful in elucidating the symptomatology of schizophrenia Coriat refers to the extensive investigation of focal infection and mental disease undertaken by Kopeloff and Kirby These writers found that in 120 cases of various types—manic depressive insanity dementia praecox, psychoneuroses etc—the focal infections were removed in 58 cases, but this did not result in a higher percentage of recoveries than in the other group of 68 cases in which the focal infections were not treated He concludes that while it is desirable to remove focal infections in mental patients, as one would treat any other physical disorder, it has not been shown that focal infection is the etiological factor in functional psychoses

293 **Salvarsan Treatment of Multiple Sclerosis.**

H SCHAFER (*Deut med Woch*, August 29th, 1924 p 1178) has treated several cases of multiple sclerosis with salvarsan preparations, on the assumption that the disease is due to a spirochaete In 21 cases of typical multiple sclerosis, with a negative Wassermann reaction in the blood and cerebro spinal fluid, he gave silver salvarsan the initial dose being 0 05 gram, and the final dose from 0 15 to 0 2 gram Two injections were given every week, and the average total dose was 2 5 grams In 13 of these 21 cases (62 per cent) objective signs of improvement were demonstrable, the symptoms most amenable to this treatment were the spastic and paretic ones the intention tremor, nystagmus, and disturbances of the bladder and rectum In an earlier series of cases treated in hospital during the past twenty years by other measures such as baths rest cures electricity and the administration of iodine arsenic and silver, and by injections of fibrolysin the results were not so good In this series there were 135 cases of multiple sclerosis and only 34 of them (25 per cent) showed objective improvement The author has also given neosalvarsan in 19 cases, but has not seen any very encouraging results therefrom

297 **Paralysis of Brachial Plexus after Serotherapy**

J LEPINE (*Journ de Med de Lyon*, June 24 th, 1924, p 351) reports two cases of this condition The first a man aged 30, of excellent health had had an injection of antitetanic serum when wounded in 1915 In 1922 his right hand was crushed and he had another injection of antitetanic serum Eighteen days later he experienced great pain in both arms, especially the right with some contracture and very slight trismus When Lepine saw the man three months after the accident the violent pains had gone but there was still some pain and formication in the shoulders and arms There was slight diminution of sensibility in both shoulders in the distribution of the fourth cervical root, and a marked motor impairment in the upper arms but none in the forearms and hands Tendon reflexes were absent in the upper limbs and diminished in the lower limbs There was atrophy of the trapezius and deltoid and some winging of the scapulae The second case a man aged 51, also of robust health, had an injection of antitetanic serum following a fall on his right shoulder Eight days after the accident severe pain was felt in the shoulders and arms, the intensity being greatest in the right shoulder Four months later he had no appreciable atrophy or definite paralysis but the pain persisted in the shoulders involving especially the trapezius and occipital muscles, and immobilizing the neck and the right shoulder In Lepine s experience the prognosis in these cases is good, though their progress may be very slow He does not think the phenomena are anaphylactic in their nature, nor considering their rarity, that they are due to faulty serum—for example the presence of insufficiently neutralized tetanus toxin For mild cases he has found rest, sedatives at first nerve tonics later, the cautious use of strychnine (arsenic is to be avoided) gentle massage and light baths sufficient For amyotrophic cases the continuous current is indicated On account of a tendency to contracture faradism is contra indicated

233 **Progressive Lenticular Degeneration (Hepato-lenticular Degeneration)**

J G GREENFIELD I J POYNTON, and F M R WALSHE (*Quart Journ of Med* July, 1924 p 385) give a useful summary of the clinical and pathological investigations of this affection during the last ten years, based on 30 recorded cases They also describe a further case, with a report of the pathological examination The disease was first described by S A Kinnier Wilson in 1912, and named by him progressive lenticular degeneration (it is often described as Wilson s disease) The chief symptoms are tremor (resembling that of paralysis agitans), rigidity, dysarthria, dysphagia, anarthria, spasmodic weeping and laughing slight dementia no qualitative changes in the reflexes no true paralysis no affection of sensation The onset is in youth or early adult life, the duration is one to three years and the disease is always fatal Bilateral symmetrical degeneration of the lenticular and caudate nuclei of the brain and in all cases marked multilobular cirrhosis of the liver (clinically latent), have been found by pathological examination The investigations of the last ten years have shown that the changes are not invariably confined to the corpus striatum Nevertheless, within the corpus striatum the brunt of the disease process (indicated by atrophy and degeneration of nerve cells and overgrowth of neuroglia) falls upon the putamen and to a less extent upon the caudate nucleus The cardinal symptoms are muscular rigidity and tremor, but three main types of motor disorders may be met with—rigidity alone rigidity with tremor or torsion spasm In the new case reported, a girl of 14 developed progressive dysarthria, inability to keep the mouth closed, dribbling of saliva, mask like countenance spasmodic weeping and laughter impaired movements of face and tongue muscles, flexed attitude of arms and hands There was no paralysis, and the reflexes and sensation were normal Later she developed complete anarthria rigidity of face and arm muscles flexion of trunk and limbs tremor of hands, and finally rigidity of legs with slow flexion extension movements Death occurred in twenty months The liver presented multilobular cirrhosis of a rich cellular type In the brain marked shrinkage of the corpus striatum was found, involving the putamen of the lenticular nucleus and the caudate nucleus Microscopic examination revealed degeneration of nerve cells and increase of neuroglia in these regions

Obstetrics and Gynaecology.

299 **Blood Transfusion in Gynaecology**

O KHOOI (*Zentralbl f Gynak* August 2nd, 1924 p 1714) denies the value of blood transfusion in those acute and chronic anaemias which are gynaecological in origin He has investigated the red blood corpuscle count and the haemoglobin index very thoroughly and has examined the patient s blood before transfusion and subsequently at intervals of one, two four, and six hours, then at daily intervals and finally on alternate days In the acute cases, which for the most part, were ruptured extrauterine gestations he finds that the improvement in colour the fuller and more rhythmic pulse, and the slower and deeper respiration, which are described by several observers as the result of transfusion, are only transitory, if they occur at all and he thinks they are probably due to the Trendelenburg position and ether anaesthesia In cases not transfused, as well as in some of the transfused the haemoglobin index rose appreciably some days after operation He avers that the transfused blood does not possess full physiological properties, especially as regards gaseous exchange, but on account of the serum acts similarly to transfused saline solution In all his non transfused cases (45) the patient recovered from the shock without any transfusion being required Rigors followed transfusion in all cases and the temperature remained high for six days in some cases, though usually it fell on the day following transfusion For these reasons and also on account of haemoglobinuria (a dangerous complication) occurring in some cases, the author does not recommend transfusion, the effect of which seems to him to be at the best transitory only, except in a few specially selected cases In the chronic cases of anaemia due to fibroids, chronic metritis etc similar results were obtained and rigors again occurred, followed by cyanosis, breathlessness and severe headache in many cases Instead of transfusion in such cases the injection of a small amount of blood several weeks after cessation of bleeding has proved very beneficial No case was seen for which transfusion was an absolute necessity

300 **Diagnosis of Early Ectopic Pregnancy**

A SIPPEY (*Journ de Med et de Chir Prat* September 10th, 1924 p 615) states that the pain associated with unruptured ectopic gestation is characterized by its constant presence during the waking hours, even when the patient is lying down and by its stationary position in a strictly limited portion of the pelvis Vaginal haemorrhage in the early stages is slight, almost continuous and augmented by exertion Both pain and haemorrhage increase with the passage of time These symptoms especially if accompanied by breast symptoms and signs, point to ectopic pregnancy even if—as is often the case—no history of a missed period is forthcoming In cases of tubal as of uterine pregnancy bimanual examination shows enlargement of the uterus and softening of the cervix but in the first named condition a juxtauterine tumour is palpable in one or another vaginal cul de sac Diagnosis from adnexal inflammatory conditions is particularly difficult when the tumour has fallen in the pouch of Douglas In this connexion it is to be remembered that patients suffering from adnexal inflammation do not often conceive and that the presence of a unilateral tumour and the absence of muco-purulent discharge of pyrexia and of leucocytosis point to the existence of a tubal pregnancy

301 **Cancer of the Uterus and Pregnancy**

A MAYER (*Deut med Woch* July 25th 1924 p 1003) publishes statistics controverting the popular view that carcinoma runs a peculiarly malignant course when associated with pregnancy Among about 1 600 cases of carcinoma of the uterus the author has seen 31 cases in which it occurred during or very shortly after pregnancy and these cases were certainly not characterized by great malignancy

The statistics of Martius confirm the author's views of 18 cases of *carcinoma of the cervix* 88 9 per cent were operable, whereas of 725 non pregnant cases of carcinoma of the cervix only 65 3 per cent were operable Of 12 cases of carcinoma of the cervix associated with pregnancy and operated on, only 25 per cent relapsed, whereas a relapse occurred after an operation in as great a proportion as 48 per cent of the 340 *cases of carcinoma of the cervix not associated* with pregnancy Turning to the treatment of carcinoma of the uterus and the respective merits of *x* ray treatment before or after an operation, the author argues in favour of *x* ray treatment before operation This procedure arrests the superficial decomposition of the growth and banishes the discharge, with the result that the risk of post operative peritonitis is reduced Among 67 cases, several of which were given pre operative *x* ray treatment, there was an operation mortality of only 7 4 per cent, the incidence of peritonitis being only 4 4 per cent As the operation mortality without pre operative *x* ray treatment usually ranges from 10 to 20 per cent, pre operative *x* ray treatment marks a definite advance

302 The Ovaries after Hysterectomy

ALICE F MAXWELL (*Journ Amer Med Assoc*, August 30th, 1924, p 662) analyses in detail the end results of 500 hysterectomies In 329 cases the ovaries were removed, while in the remaining 171 cases they were retained Post operative *vasomotor symptoms occurred in 80 per cent of the former* class, while in those patients whose ovaries were retained vasomotor disturbances occurred in 42 per cent only The disturbances were classed as "severe" in 30 per cent of the former and in 12 per cent only of the latter The average duration of vasomotor disturbances was practically identical in the natural menopause (2 5 years), in hysterectomy with removal of ovaries (2 7 years), and in hysterectomy with retention of ovaries (2 25 years) In 11 per cent of these cases of vasomotor disturbance the symptoms persisted for a period of *from four to seven years, contradicting the* impression *that these phenomena are transient* The retention of ovarian tissue appeared to be a distinct advantage to the patient in only 7 per cent of the 171 cases in which the ovaries were retained was there any subsequent ovarian enlargement, and in only two cases was there transient pain In every case pain and swelling disappeared within six months No neoplastic degenerations were found nor were any secondary operations performed in the entire series The author draws the following conclusions (1) The frequency of vasomotor symptoms after hysterectomy is increased when both ovaries are removed (2) The frequency of symptoms with conserved ovaries after hysterectomy compares favourably with that of the normal menopause (3) Severe vasomotor symptoms are more common without than with ovaries (4) *The onset of delayed symptoms indicates that a definite* number of conserved ovaries will atrophy within a year after operation (5) The average duration of symptoms of the normal and surgical menopause is about two and a half years (6) Women with a low haemoglobin index are more likely to develop post operative disturbances (7) The frequency of symptoms depends largely on the healthiness or unhealthiness of the retained organs (8) Retained healthy ovaries are not susceptible to degeneration

Pathology.

303 Insoluble Bismuth in the Prevention of Syphilis

W KOLLE (*Deut med Woch*, August 8th, 1924, p 1074) records experiments with mercury and bismuth given to rabbits previous to inoculation with syphilis It was anticipated that the two metals would be equally effective in aborting experimental syphilis, but it was found that mercurial preparations were comparatively inert When, however, twenty six rabbits were given intramuscular injections of insoluble preparations of bismuth, which remained as depots in the body, artificial inoculation of the testicles with the spirochaetes of syphilis never led to the development of a chancre, even when the interval between the injection of bismuth and the attempted inoculation was as long as two to fifteen weeks The *x* rays showed that such insoluble preparations of bismuth as the carbonate remained as depots in the muscles for months Control tests were carried out with sixty eight rabbits who were not given a preliminary intramuscular injection of an insoluble salt of bismuth, and 94 per cent of these rabbits developed a primary chancre Rabbits given injections of easily absorbed preparations of bismuth were found not to be subsequently immune to experimental inoculation with syphilis The author recognizes the possible importance of *these observations on the prevention of syphilis in man, but* he insists on the need for caution and not assuming that these observations on rabbits are applicable to man He also points out, in connexion with the prophylactic administration of arsenical preparations, that the failure of a typical chancre to appear is not proof positive that a mild, abortive, or latent infection with syphilis has not occurred

304. Production of Ramifications in Diphtheria Bacilli

IN *the course of their* research into the production of diphtheria toxin anaerobically, L MARTIN, G LOISEAU, and V GIDON (*C R Soc de Biologie*, July 5th, 1924, p 332) made cultures of diphtheria bacilli in Martin's broth covered by liquid paraffin They found that at the junction of the broth and paraffin a thin bacillary layer developed which grew thicker subsequently, showing no tendency to break up and fall to the bottom of the tubes even at the end of several months At the end of twenty four hours the bacilli in this layer were of the normal type, but on the second day they became elongated and lateral branches appeared About the *fourth or fifth day of incubation* these ramifying forms reached their maximum development They were very numerous, and were often grouped together, though some remained isolated and stained deeply by Gram's method, particularly at the extremities, which appeared club shaped The greatest length of the isolated organisms was 11 3*μ* From the eleventh to the thirteenth day the appearance was very little changed, except that the length and breadth of *the filaments had increased, by the sixtieth day,* together with the ramifying forms there were irregular circular masses, stained by Gram's method and separated by unstained areas This appearance remained unaltered after five months' incubation If, however, the cultures after seven days' incubation were kept at the laboratory temperature *the appearance underwent no change at first,* but at the end of five months the ramifying forms had almost completely disappeared, leaving some Y shaped bacilli, some elongated forms, and numerous bacilli of ordinary appearance Cultures taken from this layer at varying intervals up to the end of five months and inoculated on coagulated serum gave in less than twenty four hours numerous colonies of diphtheria bacilli of the normal type The interpretation of the appearance of these *ramifications is admittedly difficult, but* the authors differ from the majority of observers, and believe that they are not to be considered evidences of degeneration, since their development is regular, then staining properties are retained, and these forms appear in such large numbers

305 The Metachromatic Granules of the Diphtheria Bacillus

STUDYING the nature of the metachromatic granules formed by the Corynebacteria, K L PESCH (*Centralbl f Bakt*, July 15th, 1924, p 208) endeavoured to ascertain the chemical constitution of these bodies Since *there is a considerable* amount of evidence that they consist of nucleic acid, free or in combination, he attempted to grow diphtheria and diphtheroid bacilli on a medium free from phosphorus This medium was very difficult to prepare, and even after several attempts he was unable to rid it of every trace of phosphorus However he *found that though this trace* was sufficient to enable growth to occur, it was not enough to allow of the formation of metachromatic granules He then tried growing bacilli which were naturally poor in metachromatic granules on a medium which was enriched with phosphorus or with nuclein Compared with control media to which neither of these bodies had been added, the formation of metachromatic granules was rather better on the enriched media He concludes that the production of *volutin*—the substance of which the granules consist—can be increased by the addition of either nuclein or phosphorus, and that therefore it is probable that volutin is built up out of nucleic acid combinations Studying further the quantitative production of granules on different media, he found that whereas the granule formation is good on blood agar, and still better on Levinthal agar, it is extremely poor on ascitic fluid agar Now the actual growth of the organism is very good on this last medium, on the other media it is not so good, particularly on Levinthal He concludes, then, that there is an inverse relationship between *the growth of the bacillus* on a given medium and its production of metachromatic granules, to this generalization Loeffler's medium is a partial exception Finally, he endeavoured to find a medium which should be more suitable for use than the present Loeffler serum Large numbers of nose and throat swabs were streaked on different media, including Klein's serum alkali albuminate agar, blood agar, and Loeffler's medium, and the number of positive diphtheria results calculated *It was found that the* highest percentage of positives was obtained by growth on Loeffler's serum, and the author concludes, therefore, that at present there is no medium which is more suitable for general use than this

Fine products—each the original and standard in its own field—from the celebrated laboratories of E SCHERING

ATOPHAN

TRADE MARK

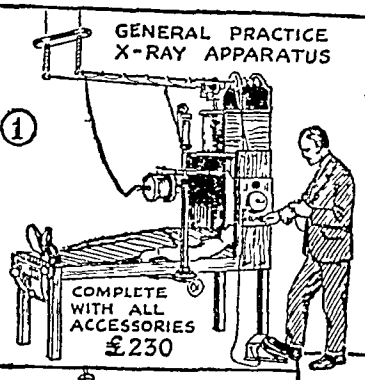
The *original* preparation which has the property of stimulating the excretion and arresting the formation of uric acid to a degree hitherto unknown

A large volume of evidence shows the value of Atophan in the treatment of **acute and chronic gout, rheumatism, and all affections associated with the uric acid diathesis**

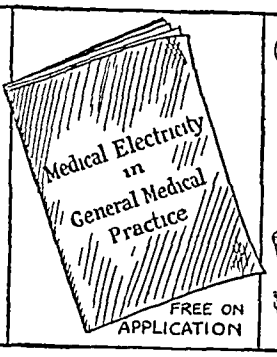
Atophan is a powerful analgesic, antipyretic and antiphlogistic, and, in addition, it exercises an astoundingly rapid stimulating action on the hepatic functions

ATOPHAN COMBINATIONS

ICTEROSAN For catarrhal jaundice cholangitis cholecystitis etc One injection is usually sufficient to produce an immediate flow of bile
In ampoules of 5 c c



ARCANOL A combination of Atophan and Acid Acetyl Sal, which has proved of great value in influenza and all diseases associated with chill
In tablets of 1·5 grs



ATOPHANYL
For injection The parenteral administration of Atophan in this form is especially indicated in rheumatism sciatica, neuralgia neuritis, etc The action is prompt and extremely vigorous
In ampoules of 5 c c

Pure Wool Sheets

The public often assume that a wool sheet is merely a modified blanket and are inclined to reject it on that account The actual facts are —

1 A wool sheet is of lighter smoother fabric even than the flannel shirt worn next the skin Jaeger Wool Taffeta especially has a surface as smooth as cotton
2 It conducts heat very much less than cotton and is therefore cooler in Summer and warmer in Winter
3 It is delightfully comfortable helps to retain health and is of particular value for an invalid

Intestinal Disinfection

No. 8

ALIMENTARY TOXÆMIA AND ENDOCRINE INSUFFICIENCY

A WRITER in *The Lancet* (May 13th, 1922) has directed attention to an apparent connection between alimentary toxæmia and endocrine insufficiency, particularly of the thyroid gland Many cases of "ill-health," neurasthenia, and others, were benefited by the administration of thyroid extract

He goes on to remark that there seems to be a close connection between endocrine insufficiency and poisoning from intestinal absorption, and notes the beneficial results obtained by the use of intestinal antiseptics in addition in these cases

He seems to be unaware that the best of all intestinal antiseptics is KEROL. In endocrine insufficiency, therefore, use KEROL in addition to other measures

For intestinal disinfection, use Kerol Capsules (keratin-coated) they contain 3 minims of Kerol One to three Capsules may be given three or four times a day after meals

KEROL CAPSULES

HOTEL PARK GEMMI — Boys (2 of 1)

ADELBODEN.
HOTEL HAHNEL — — (Boys over 16)

KANDERSTEG.
HOTEL BELLEVUE — Girls over 14.)

Each of the above Hotels have their own resident Instructor for the Camps.

Practically every Public School in the Kingdom has now been represented at these Camps.

Past Campers are unanimous in saying that they never had such a holiday in their lives, combining as it is of skating, skiing, tobogganing, curling competitions, etc., and the evening meetings.

I have made these Camps known to all parents, public and preparatory schools, and scores of letters testify what a success they have been.

The SECRETARY, Varsities and Public Schools Camps, C.S.S.M. House, Warwick Lane, London, E.C.4.

KANDERSTEG (Winter Sports) CAMPS

First Camp December 29th to January 12th, and Second Camp January 12th to January 26th.

The Winter Sports Parties (Camps) are held at the Hotel Victoria, the Largest and best appointed Hotel in Kandersteg, reserved exclusively for the Camps.

It is fair to say that the Camps in both seasons have been pronounced by all participants to be the most enjoyable holidays they have ever had.

Inclusive cost **£17 17s.**

2 PARTNERSHIP —SOUTH OF ENGLAND — In a large flourishing Seaport Town a fourth Partner is required in a lucrative mixed class PRACTICE, averaging about £5 000 per annum panel of nearly 3 000 The sixth a year is for disposal Visits guineas Comfortable rooms at the Surgery are available for the ingoing partner Premium required for share 2 years purchase Golf tennis etc, and there is scope for development

3 HAMPSHIRE —DEATH VACANCY — A very old established mixed general country PRACTICE situated within 7 miles of a large town and held by the late Incumbent over 10 years A steady average income of £1 039 including appointments and panel or about 100 Good scope for increase Advice and medicine from 2/6 visits 5/ to 20/ medicine extra Very little midwifery House contains lounge hall dining room drawing room consulting room and dispensary 5 bedrooms 2 bathrooms lit with petrol gas Garage Hall an acre of garden Free hold price £1 500 or offer Excellent hunting shooting fishing etc The practice is eminently suitable for a man fond of sport A moderate premium will be accepted There is a locum in charge

4 WEST RIDING —HOSPITAL TOWN within easy reach of University City Well established middle and working class PRACTICE averaging about £2 000 per annum, including panel of nearly 1 200 (rapidly increasing) Suitable house available Premium 1½ years purchase, payable £1,800 down, and balance by instalments

5 KENT.—SMALL TOWN within one hour of London Old established mixed general PRACTICE Average income about £1 800 including valuable appointments probably transferable and panel of nearly 1 200 Fees 3/- to 10/- Twenty cases of midwifery yearly at 2 to 5 guineas Excellent house containing 2 reception and 8 bedrooms separate entrance to professional rooms standing in its own grounds of ¾ of an acre with full sized tennis court, etc Vendor's freehold price £2 300 Good Hospital in town and Vendor on the Staff Premium £2 700 Introduction considered up to six months

6 RESIDENTIAL TOWN within 100 miles of London Non-dispensing calling better class PRACTICE, producing an income of about £2 000 a year including small panel of about 600. Fees from 2/6 to 21/, mainly 7/6 upwards Only a few cases of midwifery yearly at 2 to 25 guineas Attractive and commodious house (3 reception, 7 bedrooms etc garden) on rental at £100 p.a. Good society and sport of all kinds Premium £4,000 payable £2 000 cash and £2,000 by instalments

7 HOME COUNTY — Hospital Town within 50 miles of London PARTNERSHIP A one-half share in a mixed general practice held by senior partner 25 years Average income over £2 000 Panel of 780 Advice and medicine from 2/6. Visits and medicine from 3/6. Very little midwifery Detached double fronted house with ample accommodation and good garden Price £2,000 of which £1 000 can remain on mortgage. There is an up-to-date Hospital and an early vacancy on the staff is probable. Good sport, schools etc. Premium 2 years purchase half by arrangement.

8 EASTERN COUNTIES —Within 1 hours' run of London Practically unopposed PRACTICE old established and situated in a very pretty Country Town with beautiful surroundings Cash receipts for last financial year £2 022 including appointment of £50 and panel of 800 Visits up to 21/ Very little midwifery Car optional Railway station Charming residence (with ample accommodation) in its own grounds of ¾ of an acre. Price £2 900 all of which can remain on mortgage at 5 per cent Premium for practice £2 500 Excellent prospects Tennis golf, hunting, shooting, etc

9 NEAR LIVERPOOL —In a large town (population nearly 100 000) close to seaside resort, an old established flourishing and increasing PRACTICE worth last year £2 100 including 1 600 panel patients. Visits 2/6 to 5/ Midwifery 2 to 4 guineas about 100 cases yearly Vendor's property, and can be purchased Premium

10 FAVOURITE INLAND SPA —PARTNERSHIP A well-qualified and experienced man, with a good personality is desired by a Consulting Physician as Partner with ultimate succession The present income is only about £1 500 a year but there is very considerable scope for increase and the newcomer would be encouraged to undertake general practice without accountancy, to the partnership for the fees so obtained. There is a choice of houses both on rental and to buy in the residential part of the town At present the fees are mainly 1 and 2 guineas but there are a few at 10/6 Premium for the half share £1 500

11 GROWING COAST TOWN within easy access of London Old established very sound mixed general PRACTICE Average income over £1 800 Fees mainly 3/6 to 10/6. Very little midwifery Very good corner house with small garden There is a Cottage Hospital in the place and the Practice offers very good prospects to a Surgeon Premium 1½ years purchase

12 WEST CENTRAL —Sound, easily worked PRACTICE of about £770 a year There is very good scope as the Vendor has suffered from ill-health since the war Fees mostly 10/6 Very convenient flat Rent £58 Premium £1 100.

13 LONDON NORTH —Old established PRACTICE producing an income of £1,400 a year including appointments worth £320 Panel of 300 but this can be largely increased if desired Visiting and medicine 3/6 to 7/6 Practice is easily worked with no conveyance. Nice house in good decorative repair with fair garden Rent £125 Garage can be let off at £20 or £51 Premium £2,000

14 NEWCASTLE UPON TYNE AREA.—Old-established PRACTICE held by Vendor many years Steady average income of about £3 350 There is a Hospital in the town and a reasonable prospect of obtaining an appointment on the Staff. There are various appointments worth about £150 a year Very little midwifery but large scope if desired Fees 1/6 to 21/ House is Vendor's freehold it is well situated and will be let or sold Excellent educational facilities Premium to include drugs, etc., only £3 000, payable £2 000 down

15 MIDLANDS.—LARGE MANUFACTURING TOWN —Old established PRACTICE producing about £1 000 per annum Visits from 3/6 Not much midwifery lowest fee 2 guineas Large commodious house Price, freehold £1 500 Premium 1½ years purchase.

16 MIDLANDS —In a delightful Town (population over 15,000) amidst beautiful surroundings and within 1 hours' run of London, an old established lucrative PRACTICE worth over £3,300 per annum including large panel. Good fees The house is well situated has ample accommodation and can be rented on lease at £100 a year Premium £3 000 cash and £2 000 by instalments Satisfactory reasons for selling Educational facilities and sport of all kinds.

De Dion Bouton

THE MOTOR SHOW.

THERE will be many hundreds of cars to examine, and, if you have patience, a score of goodly tales to listen to from eager salesmen making a bid for your franchise But there is none to give you welcome like De Dion' Proudly the boast "It is a Doctor's Car has carried down De Dion's forty years of service to the Medical Profession Experience has brought a full knowledge of your needs, and tradition sets a standard of comfort and quality that earns the eager appreciation of the most undemonstrative owner

Five Cars will be exhibited at Olympia, and eleven at 10, Gt Marlborough Street For the sake of colour harmony the Olympia Cars have been confined to the Brown Field of colour, in, of course varying shades and tone blends For a complete survey a cordial invitation is extended to the fuller exhibition at 10, Gt Marlborough Street, where will be seen the many beautiful effects achieved by the London Coach Craftsman

Complete Cars from £475

TRADE MARK 'TABLOID' BRAND

'EMPIRIN' COMPOUND

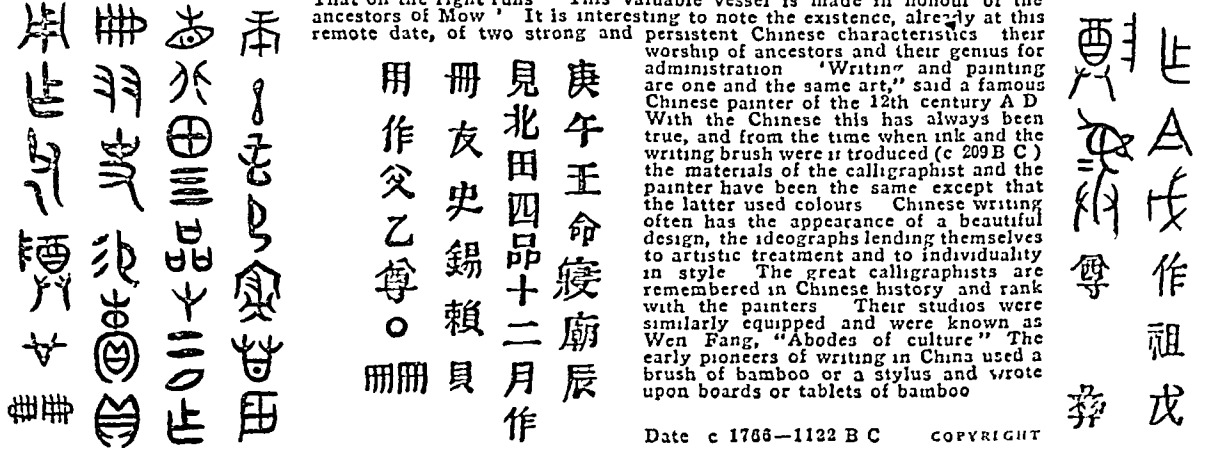
(Trade Mark)

℞
'Empirin' (Acetylsalicylic Acid) gr 3-1/2 (0 227 gm)
Phenacetini, gr 2 1/2 (0 162 gm)
Caffeinæ, gr 1/2 (0 032 gm)

Supplied to the Medical Profession, in bottles of 25 and 100 at 1/3 and 3/9 per bottle, respectively

Prepared at the 'Wellcome' Chemical Works from Acetylsalicylic Acid, of the highest purity, entirely free from salicylic or acetic acids, and having a melting-point considerably higher than officially required

Disintegrates immediately, and causes no gastric disturbance



When the physician deems it undesirable that the patient should have knowledge of the treatment, 'TABLOID' 'EMPIRIN' CO. is a convenient prescription

EXAMPLES OF THE MOST ANCIENT EXTANT CHINESE RECORDS.—The large body of literature purporting to be contemporaneous records of about 1800 B C has been found to be no more than based upon such records If they ever existed in written form the original script has disappeared and the records were reproduced in that of the much later time in which they were written The only authentic writing of this ancient period is that found upon bronze vessels which themselves belong to that date The inscription here reproduced on the left, together with the same characters in their modern form, reads "During the 12th month of the year Kăng-woo his Majesty, in consequence of meritorious conduct, rewarded the Yew she officer of the fourth rank (who presided over the Northern Agricultural Department) and gave him this valuable Vase to be used when worshipping his ancestors" That on the right runs "This valuable vessel is made in honour of the ancestors of Mow ' It is interesting to note the existence, already at this remote date, of two strong and persistent Chinese characteristics their worship of ancestors and their genius for administration 'Writing and painting are one and the same art," said a famous Chinese painter of the 12th century A D With the Chinese this has always been true, and from the time when ink and the writing brush were introduced (c 209 B C) the materials of the calligraphist and the painter have been the same except that the latter used colours Chinese writing often has the appearance of a beautiful design, the ideographs lending themselves to artistic treatment and to individuality in style The great calligraphists are remembered in Chinese history and rank with the painters Their studios were similarly equipped and were known as Wen Fang, "Abodes of culture" The early pioneers of writing in China used a brush of bamboo or a stylus and wrote upon boards or tablets of bamboo

OPINION is still divided as to how the ill consequences of intestinal sluggishness are brought about But as to the reality of these consequences there can be no doubt Equally obvious is the almost magical clearing up of the physical apathy, psychic depression, and general feeling of malaise when effective steps are taken to remedy the constipation that caused them

Although it is to exercise and to modifications of diet that we should look for a permanent cure these commonly—and almost invariably in the earliest stages of treatment—need to be supplemented by other means Left to himself, the patient is apt to resort to drastic purgatives which, in the long run often do more harm than good All that is necessary can be achieved, without any ill after effect by means of a spoonful of ENO's "Fruit Salt" taken each morning in a glass of water for as long as may be expedient This preparation, which contains no mineral aperient is agreeable and refreshing to the palate, occasions no pain or nausea, and is manufactured with every precaution to maintain absolute uniformity and purity

THE Proprietors of ENO's Fruit Salt will on application to any member of the Medical profession send a bottle (Handy or Household size as desired) of their preparation together with a copy of "The Practitioner's Pocket Book" This book is written with "The Duty of Prescribing" in mind and thousands of copies have been sent on request to medical men many of whom have expressed their thanks for a preparation of such utility,

THE PRACTITIONER'S POCKET BOOK"

embodies in a concise form many practical axioms of value and use to the practitioner and contains legal points of great importance to every doctor and the essentials of many chemical processes involved in general practice pathology

J C ENO LIMITED, VICTORIA EMBANKMENT, E C 4

18 YEARS' TEST OF Roboleine

EVER since "Roboleine" was introduced to the Medical Profession the demand for it has steadily increased This fact proves beyond doubt that both in constitution and in balance "Roboleine" conforms to the ideas of the general body of Medical Practitioners

Those members of the Profession who have not yet proved for themselves the excellent properties of "Roboleine," are asked to consider its constituents, and to write for clinical sample and literature

ROBOLEINE CONSISTS OF:

MARROW from the long bones of prime oxen, RED MARROW from the rib bones, "CREAM of MALT" (described by "The Lancet" as the creme de la creme of malt extracts') Egg Yolk, and Neutralized Lemon Juice

The Governor of the London Hospital says
"The effect on some of our anæmic and rickety children has been MAGICAL."

Clinical Sample and Literature on request

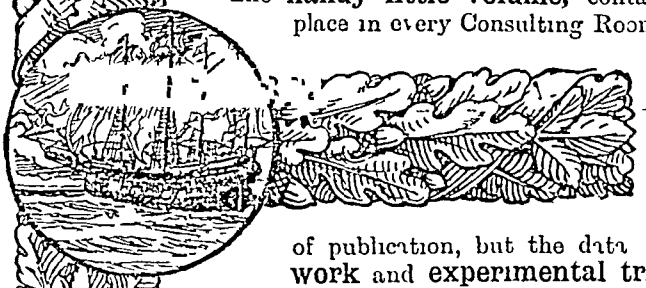
London EDWARD ARNOLD & CO, 41 & 43, Maddox Street, W 1

Vol. I (1924) of the Extra Pharmacopœia



By MARTINDALE & WESTCOTT,

is now ready, **27/6** *net*, *post free*, **28/-**

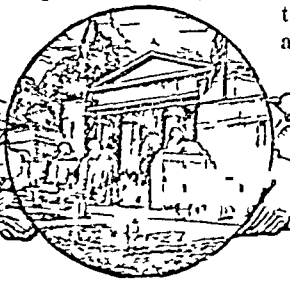
The book embodies the results of a vast amount of research in **Chemistry, Pharmacology,** and the closely **allied sciences**

It is claimed that **no modern Medicinal Chemical, Drug, Organotherapeutic agent** or **Vaccine,** worthy of inclusion, has been **omitted**

The **handy little volume,** containing 1,163 *pp* xxxviii pages, should find a place in every Consulting Room, Pharmacy, and Laboratory, as a reference book in matters appertaining to the therapeutic use of drugs and chemicals

Not only is the medical and chemical literature, one *might say* almost of the world, summarised concisely, up to within a week or two of publication, but the data are given concerning **practical laboratory work** and **experimental trials** of **new therapeutic agents** not to be found in other treatises

It is only possible to give an outline of some of the new information



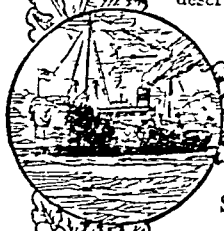
NEW CHEMICALS, DRUGS, AND METHODS OF TREATMENT.

ALKALOIDAL NOTES This chapter contains some interesting observations regarding **"Activated" Alkaloids** and, in addition, the description of a series of **Alkaloidal Periodides** The preparations may, in both cases, be useful additions to the physician's armamentarium

ASPIRIN COMPOUNDS, include therapeutic notes upon various new halogen derivatives

BISMUTH, ORGANIC COMPOUNDS The "pros and cons" of these competitors of mercurials, and their chemistry, are described in six pages

COLLOIDAL METALS The chapter contains, as new, **Colloidal Calcium, Colloidal Lead,** also notes upon the **Collodial Gold** treatment of neurasthenia, alcoholism, and the morphine habit



EMETINE & ITS COMPOUNDS —Fifteen pages are now devoted to these Emetine Periodide and a variety of supplementary remedies for use in amœbic dysentery are described

ACCESSORY FOOD FACTORS —The information under this heading runs to ten pages, clearly subdivided under the sections 'Factors A, B and C'" Practical hints are given for making preparations of each, to retain the factors unimpaired by heat, aeration, etc

CHAULMOOGRA COMPOUNDS —New suggestions for injections for use in leprosy, etc, including compounds of the Ethyl Ester type

INSULIN —The subject of diabetic treatment with this is described in eight pages under such headings as Manufacture, Units, Technique of Injection,

Suitability of Case, Contraindications, Effects of Excessive Dose, Clinical Experience, and so on

NON-IONISABLE MERCURIALS (Mercurochrome, Flumerin, and allied bodies) are fully dealt with

QUINIDINE AND CINCHONIDINE in malaria, as also in heart affections, are concisely commented upon

---

VACCINES AND ANTITOXINS —The matter on these now runs to seventy five pages It has been completely overhauled and rendered up to date New Tuberculins call for mention.

ORGANOTHERAPY —Thirty pages are devoted to Endocrinology and treatment with animal products in general In particular attention may be drawn to the chapters on Pituitary, Thyroid, Parathyroid, and Suprarenal.

INTRAVENOUS DOSE TABLE —A useful guide to this method of medication, which offer such great possibilities in the future

DANGEROUS DRUGS ACTS —A concise summary including Calculation Tables, carefully enunciated directions for the medical man and pharmacist Examples of Procedure by actual prescriptions, "Signed Orders," and the like A New Sign is introduced showing every "dangerous" drug throughout the book

The work is, in effect, of unique value to the prescriber and the chemist

---

Hold the container with the left hand—

Rotate the flange of the inner portion of the container in the direction of arrow until gauze appears—

Draw out sufficient of the Dressing for immediate use and not more and cut away about half an inch from container—

Rotate the flange in opposite direction (as arrow) until the gauze is quite covered

The Steraid series are packed in special patented Cartons or Containers. Any dressings packed in similar containers and not bearing this Trade Mark should not be accepted. Manufacturers, Vendors and Purchasers are liable for infringement.

STERAID

REG.

SERIES OF

ABSORBENT AND MEDICATED GAUZES

MADE IN ENGLAND

An entirely new and original departure in the packing of Surgical Dressings

This series is offered to provide a Surgical Dressing which after packing retains its aseptic condition more nearly approaching perfection.

The dressings after being placed in the Patent Containers are not handled or exposed to the atmosphere again.

In use only the amount required is drawn out and cut off, the remainder of the contents is not exposed or handled, the whole operation being exceedingly simple and consisting of four motions only—twisting in either portion to expose end of dressing, drawing out sufficient quantity, cutting off, rotating to close.

The Steraid series offers a great advantage over all other forms of dressings. Sufficient of the dressing for the immediate application and the remainder promptly re-sealed in the Patent Container, thus obviating the risk of exposure to dust and germs in the atmosphere. It occurs when the whole of the dressing has to be removed from a tin or package.

Medicated Gauzes should be preserved from the light as being made they deteriorate. The Steraid series will be found eminently suitable for such dressings.

Do you Sing in your Bath?

B23

Somebody has said "When up to the neck in hot water be like a kettle and sing"

Hot water that really invites you to song is the invigorating stream that pours in generous measure from a gas water-heater—not the long-deferred lukewarm flow from the kitchen range boiler

Why not sing in your bath for 'a mere song'?

* * *

The B.C.G.A. representing the British Gas Industry, is at the service of the public without charge, for advice and help on any subject large or small connected with the economical and efficient use of gas in home office or factory

A letter to the Secretary of this Association will receive prompt and careful attention.

VACCINE TREATMENT FOR TUBERCULOSIS

Detoxicated Tubercle Bacillus Vaccine is prepared from virulent strains of Tubercle Bacilli. The germs are subjected to mechanical disintegration in the presence of weak alkali which acts as a solvent of the liberated bacterial protoplasm. The waxy or "fatty" portion, forming an insoluble residue, is completely separated by filtration through Berkefeld filters and is discarded, consequently this preparation is a

"DEFATTED" VACCINE

as well as a Detoxicated Vaccine

(See BRITISH MEDICAL JOURNAL, *7th July, 1923)*

A large quantity of this Vaccine is now available.

The Influence of Diet and Light on the Vitamins in Milk

"*Milk from a pasture-fed cow has a definite and high anti-rachitic value, the same animal when stall fed in the dark yielded a milk much inferior in anti rachitic properties A possible contributory cause of the seasonal incidence of rickets in children may be the use of milks whose anti rachitic value is higher in summer than in winter*

The Influence of Diet and Light on the Vitamins of Milk—Biochemical Journal of 1923 xvii 735 (No 6)

The winter increase in rickets among infants in England seems, therefore, to result from the poor anti rachitic properties of the dry and artificial diet of stall fed cows, and partly from the very low value of the ultra violet rays in winter daylight These factors can be entirely eliminated by the systematic use of Glaxo

Glaxo

is made from the milk of cows which are pasture-fed in sunlight *all the year round* Experiments prove that it has a uniformly high anti-rachitic value

GLAXO (MEDICAL DEPT) 56 OSNABURGH STREET LONDON NW 1

The Original and Standard EMULSION of PETROLEUM

Angier's Emulsion is made with petroleum specially purified for internal use It is the original petroleum emulsion—the result of many years of careful research and experiment

A Perfect Emulsion.

Placed under the microscope, physicians may see for themselves how minutely and evenly the oil globules are subdivided Angier's Emulsion actually duplicates cream in appearance and consistency, and, like cream, mixes instantly and perfectly with water Bland and pleasant, it has no suggestion of petroleum, and is almost tasteless It can be administered undiluted or in any desired beverage, and may be continued for a long period without exciting distaste It is remarkably well borne by sensitive stomachs

Quality and Reliability.

Angier's Emulsion has won for itself a unique reputation for quality and reliability It has, from the first, set the standard of perfection in Emulsions, in pharmaceutical excellence and in therapeutic value it is easily first Medical men may prescribe Angier's Emulsion for their patients in the confident assurance that it is at all times, in hot weather as in cold, of uniform quality and excellence

In use Thirty-four Years.

Angier's Emulsion has been before the Medical Profession for thirty-four years, and is now extensively prescribed by Medical Men throughout the entire English-speaking world There is a vast amount of evidence to its efficacy in the treatment of pulmonary and bronchial affections, gastro-intestinal disorders, and in wasting diseases due to faulty assimilation

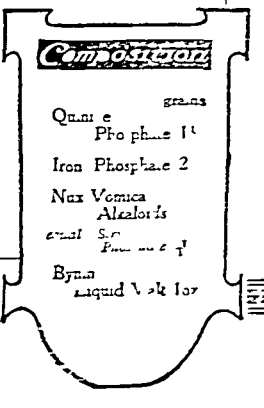
BYNIN Amara

"A Distinct Advance on Easton's Syrup."



——*The 'Lancet'*

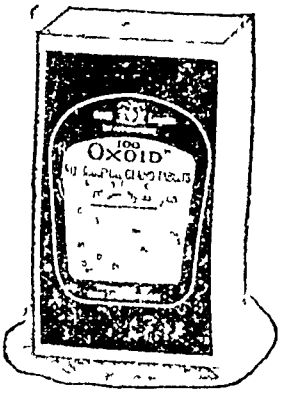
'Bynin' Amara is an analogue of the well-known Easton's Syrup, but it is therapeutically much superior to that preparation The syrup is replaced by 'Bynin,' pure active Liquid Malt, which affords a far better vehicle than the former, as it is actively digestive and nutritive An added advantage is that the nauseous flavour of Easton's Syrup is effectively masked, whilst there is no possibility of sugar crystallising out and carrying down with it the active alkaloidal principles

DOSE FOR ADULTS—A dessertspoonful to a tablespoonful in twice the quantity of water twice or on occasion three times daily

Further particulars and free sample will be sent on request.

Allen & Hanburys Ltd.
37 Lombard Street, LONDON, E C 3

"OXOID" Gland Preparations



NOTE —The word "OXOID" is the copyright of Oxo Limited, and is used to denote the Company's Therapeutical Preparations in tablet and fluid extract form

The Organo-therapeutical products of Oxo Limited are prepared from the endocrine glands of the ox. The Oxo herds are reared on pastures rich in vitamins, which are so important for the healthy development and full activity of the endocrine organs.

STANDARDISED PHYSIOLOGICALLY

"OXOID" Gland preparations are tested physiologically and adjusted to a uniform standard of activity. They are also chemically standardised in all cases where chemical methods of standardisation are applicable.

"OXOID" Gland preparations are supplied in the form of tablets and fluid extracts as follows —

TABLETS

"OXOID" Thyroid Gland Tablets
"OXOID" Pituitary „ „
"OXOID" Suprarenal „ „
"OXOID" Adrenalin „

} in bottles of 25 and 100 tablets

MAP SHOWING THE EMPIRE OF CHINA AS BUILT UP AND EXPANDED BY THE CHOU DYNASTY DUPING ABOUT 900 YEARS—The Shang dynasty fell by reason of the luxurious living degeneracy and consequent misgovernment of its last representative. The Chou dynasty succeeded it after a great battle. Its early rulers built up an empire formed of a confederacy of feudal states each governed by its own head (all relatives of the emperor who were thus rewarded for their military aid) but united under the Son of Heaven *i.e.* the emperor At the beginning of the dynasty the Chinese were constantly engaged in keeping at bay the barbarian tribes—the Huns on the north and west the Man tribes on the south—whose attempts at encroachment were persistent and formidable They enlarged the borders of their empire, which had hitherto consisted of the two states of Shensi and Shansi by gradually getting the better of these tribes in warfare or by forcing them to give up territory in exchange for goods—even in time, they mingled with them in certain parts. Before the end of the dynasty considerable tracts thus became undisputed Chinese territory The period of the Chou dynasty is the longest as well as, perhaps the most important, in Chinese history In it were evolved most of the ideas and institutions by which the Far East has lived down to modern times. The great sages of China Laotzu Confucius and Mencius lived during this epoch and contact with the West was established by the slow and painful opening up of trade routes.

Ambulatory Treatment of Fractures of the Limbs; Tuberculous and Arthritic Disease of Joints.

By CAREL A. HOEFTCKE

7, Harley Street, London, W 1

Extract from the Medical Press and Circular, *April 9th, 1924, pages 293—296*

RHEUMATICS

By an Eminent Physician

"Gentlemen—The subject you have chosen for discussion is one which, though of the greatest importance, happens to be, at the moment, very obscure and difficult

" Thus one finds as one blunders about in this swamp of 'Rheumatics' that each stone you try to step upon tilts you up and plays you false

" Lastly, there is one method upon which I would like to say a few words, though I must deal with it cautiously There are cases of severe arthritis in which the disease has become quiescent, but in which, either owing to the initial severity, or from lack of knowledge, or the character of the patient, severe contractures have resulted, one or both knees, for example, have become fixed at a right angle and the patient has been unable to walk, possibly for years These are sometimes dealt with by forcible extension and elaborate splints—a treatment associated with the name of Mr Hoefftcke No one, I think, is more afraid than I am of forcible wrenching of joints, or more cognisant of the amount of suffering that patients have to face in the course of this method of treatment I am, moreover, not a surgeon, and have not the requisite knowledge to appreciate how much value the element of traction possesses This, however, I must say, that in three out of four cases, all of the worst type, in which I followed through the results, they were eventually remarkable The fourth case, a hip-joint affected with osteo-arthritis, was a failure, but I am not prepared to alter my mental attitude because this was a failure, for the cases I am dealing with are most difficult, and there must be failure I can only repeat that I have seen three remarkable successes When I am faced by a patient with contractures of long standing, unable to walk or earn his living, I ask myself What method other than this is open to use? Gradual extension is out of the question, at least I have never seen a great success If, then, forcible extension has to be undertaken, is this splint the best, or is it unnecessary, complex, and expensive? Can we deal with these extreme cases any other way? Is the traction an important factor in eventually restoring function? I have had conflicting answers, and yet it seems to me that it is of importance, and, if so, any splint that can achieve this must, I imagine, be complicated and expensive"

Two of this Physician's cases are described and illustrated in my book, entitled "The Ambulatory Treatment of Fractures and Diseased Joints," published by Messrs Heinemann, Medical Books, Ltd, London, price 10s

---

Extract from the Medical Press and Circular, *May 14th, 1924, page 406*

RHEUMATICS

By Carll A Hollopeter

" The danger of injury does no doubt exist if the wrenching is done without extension Under such conditions the joint surfaces are pressed together by strong muscular tension, and as the surfaces are usually eroded there is serious danger of injury If, however, the joint surfaces are kept separated while the manipulation takes place this danger is avoided Such separation can only be obtained satisfactorily by an extension table or extension splint Further, the suffering which the patient has to face is in a large measure due to the contact of the diseased joint surfaces and is accordingly, greatly reduced by suitable extension Cases treated by my ambulatory extension method in arthritic or tubercular diseases need not be quiescent, in fact, the earlier the extension treatment is applied the sooner a good result can be expected "

"The Lancet," *January 5th, 1924 review* —

" And it should be stated clearly that he works only with the medical profession and not as one who offers a substitute for medical services "

The Harveian Oration
ON
THE DEBT OF SCIENCE TO MEDICINE

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF LONDON ON ST LUKE'S DAY, OCTOBER 18TH,

BY

ARCHIBALD E GARROD, K C M G, D M, I L D, F R C P F R S,

REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF OXFORD CONSULTING PHYSICIAN TO ST BARTHOLOMEW'S HOSPITAL

MR PRESIDENT AND FELLOWS OF THE COLLEGE,—More than two centuries and a half have passed since the most illustrious of our Fellows founded the festival which we celebrate to-day, and directed that an oration should be delivered by one of our number Upon the long list of Harveian Orators are many names familiar wherever medicine is studied, and amongst them those of my six most recent predecessors in my chair I esteem it a great honour that you, Sir, should have thought me worthy to stand here to-day, and to deliver Harvey's message

It will be my endeavour to follow the injunctions which he laid down to commemorate the great men of the past, benefactors not only to this College but to the human race to exhort our brethren to work together in peace and amity, and to urge them to pursue the study of our science, by methods of which he himself made such good use

Ever since this College was founded its Fellows and Members have, generation by generation, brought their several stones to the building of the house of medicine Upon its Roll are names of "men in their generation famous, and in ours never to be forgotten," men of genius whose fame as discoverers and as pioneers, in medicine and in other branches of natural science, is world wide and will never die, and of some highly distinguished in other walks of life, great scholars, such as Linacre and Caius poets and philosophers Upon it, too, are names of generous benefactors to scientific education, such as John Radcliffe and Matthew Lee, and of commanding personalities patrons of science, art, or letters, such as Richard Mead, the Mecænas of his day

But these great ones form only a small minority, and most of those upon our lists were men of lesser stature but as teachers who handed down to their pupils the treasures of their observation and experience, busy practitioners keen observers, or men of varied culture, few of them can have failed to add something to the sum of human knowledge Yet many of their names recall no memory, or have attained to that most arid form of immortality to serve as labels for malady or symptom But collectively, their work which they did counts for much, and those of us who are conscious that we shall leave no "footprints on the sands of time" may take courage from the thought that we too are helping to do the spade work for some future Harvey

On this occasion it is only fitting that special mention should be made of one born just three hundred years ago and who, although, owing to a technical obstacle now long obsolete, he was not a Fellow of this College, held its licence, and we may associate in our celebration the names of William Harvey, the physician to King Charles and the immortal founder of modern physiology, and Thomas Sydenham, the soldier of the Parliament, who did for clinical medicine what Harvey did for physiology and brought it back from the realm of fancy to the bedside study of signs and symptoms These two men, Harvey and Sydenham, each pre eminent in his own line, were wholly unlike in their outlook, and although contemporaries are not known ever to have met

Sydenham, at the mention of whose name the illustrious Boerhaave used to raise his hat, has been called the English Hippocrates, and by this College on his monument, 'Medicus in omne evum nobilis" Certainly no man ever had, in greater degree, the gift of conveying, in a few sentences, a vivid picture of a morbid state, and even though we may rejoice that those dear to us are no longer treated in accord with his prescription, we realize that he opened a new era of therapeutics To him must be assigned a high place among our benefactors

The history of medicine traces back to the birth of our race, and even beyond, for we know that the lower animals have therapeutic instincts From the outset treatment has been shaped by prevalent notions of the nature of disease, and maladies provoked by the enmity of a primitive deity, or by the malicious magic of a fellow creature, are only likely to be cured by magical methods In Osler's words "To a very definite but entirely erroneous pathology, was added a therapeutic rational in every respect had the pathology been correct" The primitive medicine and the art of the medicine man survive to this day among the savage races of the earth, and he would be a bold man who should deny their survival amongst those races which regard themselves as the highest products of civilization Are any of us wholly free from such ideas?

For ages medicine has striven to shake off her bonds, and to attain to the status of a science The first act of the drama was staged in ancient Greece We know well that the true spirit of inquiry, the desire for knowledge for its own sake, was innate in that wonderful race, of which the intellectual life centred around the city in which the people "spent their time in nothing else, but either to tell or to hear some new thing" The legacy of Greece embodies not only the Parthenon and the Erechtheum, the sculptures of Pheidias and Praxiteles the plays of Æschylus and Euripides, the thoughts of Socrates and the works of Plato Greece gave us also Aristotle and Hippocrates Only the true spirit of science could have prompted the minute and accurate research into the structure and functions of living things which are embodied in the writings of Aristotle, or the pictures of disease and its symptoms to be found in the clinical records of Hippocrates Do we not still speak of the 'facies Hippocratica" and of Hippocratic succussion?

We cannot doubt that there were forerunners of Aristotle, nor that much of the knowledge embodied in his books had been collected by lesser men Nor can we doubt that there were scientific physicians before Hippocrates, men of the schools of Cnidus and Cos, some of whose writings are included in the Hippocratic corpus Indeed, Aristotle whose lifetime overlapped that of Hippocrates bears witness to this when he speaks of physicians as men who usually base their medical theories upon principles derived from physics We must rather suppose that, like other men of genius, Hippocrates illuminated and crystallized the floating knowledge in the atmosphere of the Asklepieion But Hippocrates was something more than a man of science for when we read what he has written we realize that the most cherished traditions of our profession the rules of its conduct, were inherent in the Father of Medicine, the author of the Hippocratic oath

When at a later period, the centre of Greek medicine shifted to Alexandria, Erasistratus and Herophilus had opportunities for the practical study of human anatomy such as none had before them, and in the second century of our era the Greek tradition culminated in the life and writings of Claudius Galen, a great physician, a true inquirer of Nature, author of many treatises imbued with the spirit of Hippocrates, but not so great as he It was the strange fate of this man to be set up as an oracle to be regarded for more than a thousand years as infallible and his statements as admitting of no appeal Then after Galen the curtain fell, to be rung up again only in the sixteenth century of our era

During that long interact the races which had overthrown and overrun the empire of Rome were being educated *de novo*, to appreciate the culture which had destroyed Meanwhile, the keeping of the works of the ancient physicians passed to the Arab races and for centuries were only known in Syriac or Arabian translations, or in retranslations from those tongues into Latin Then in the end science stirred in her sleep in the thirteenth, and finally reawakened in the sixteenth century There was indeed much leeway to be made up Even as late as in the year 1559 Dr John Geynes was cited before

this College because he impugned the infallibility of Galen and was obliged to sign a solemn recantation of his error "Ego Johannes Geynes fateor Galenum, in iis quæ proposuit contra eum, non errasse" Surely, in the Elysian fields, the shade of Galen chuckled!

Great as were the achievements of the fathers of medicine, they began to construct their edifice with the bricks Their anatomy was almost wholly that of the lower animals, and the physiology of Galen seems to us grotesque The sciences upon which anatomy and physiology rest were hardly yet born If medicine were to be established upon a scientific basis the structure needed to be firm from the ground upwards, and from the sixteenth century onwards the foundation sciences, and those which form the lower stories, have been cultivated and advanced largely by medical men who saw them to be essential to the progress of their own science and art

So medicine, oldest of applied sciences, older indeed than the sciences applied, has through the ages furthered the growth of natural knowledge How profound her influence has been, and how it has been exerted, it is my present aim to show

Research and education are closely linked, but whereas from their earliest days there have existed, in the universities of Europe, the three professional faculties of *Divinity, Law, and Medicine, that of Natural Science is of* quite recent development For the student with a scientific bent two paths were open he might either attach himself to the Faculty of Medicine, or might approach his chosen studies by way of mathematics

Even down to the seventeenth century, or later, the university course in medicine was almost wholly theoretical The Professor expounded to his pupils the writings of Hippocrates and Galen, together with those of some of the great Arabians, such as Avicenna and Rhazes Such were the duties assigned by Linacre to his lecturers at Oxford and Cambridge, and those of the Regius Professors at those ancient seats of learning Thomas Molyneux (1661-1733), a young graduate of Dublin, where he was afterwards Professor of Medicine, visited Oxford in 1683, and heard the Regius Professor, Dr Luff, "read on the first aphorism of Hippocrates in the Physic School, where giving an account of the shortness of man's life since, and the length of it before the flood, he made up of Mr Burnett's fancy, not at all altered but in the word" No wonder that Molyneux was not diverted from his purpose to continue his studies at Leyden, where clinical medicine was being taught in a university clinic Elsewhere clinical knowledge was acquired by attendance upon the practice of a physician or surgeon, a system of apprenticeship which has this to its credit—that out of it has grown the English system of bedside instruction to small groups of students The first attempt to start clinical teaching within the university was made in Padua in the late sixteenth century, but the first organized clinic was that in Leyden, started in about the year 1630

The study of science for its own sake, apart from any professional applications, began again in the sixteenth century, and was active in the century which followed In this country Oxford took a large part in the renascence of pure science There Robert Boyle, the "father of chemistry," set up his private laboratory in 1654, and around John Wilkins, Warden of Wadham—the college of Mayow and Sydenham, and one to which science and medicine owe much—there gathered a group of men eager for the advancement of natural knowledge, who, with the members of the "Invisible College" in London, formed the nucleus of the future Royal Society In the same century chairs of astronomy, natural philosophy, anatomy and botany were founded in Oxford, and the Botanic Garden was established In 1657 Thomas Millington (1628-1704), a President of this College, was made Sedleian Professor of Natural Philosophy, and the first Savilian Professor of Geometry and Astronomy, John Bainbridge (1582-1643) was also one of our Fellows

How large a part members of our profession played in this reawakening of science is shown by the large proportion of medical men among the original Fellows of the Royal Society Of the total of 115, which included peers, clerics, and distinguished people such as John Evelyn and Samuel Pepys, only a small proportion were men of science in any strict sense, and of these no less than 25 were Doctors of Medicine, whilst 21 were Fellows of this College

In the reawakening of medical science Italy took the lead, and especially in the Of her universities, Padua, under the [illegible] of the Venetian Republic, became the chief centre of medical teaching in Europe, and thither repaired the pick of our English students to profit by teaching such as they could not obtain at home Later, when the star of Padua paled for a time, Leyden took its place as the cynosure of students of medicine

Of the professions open to him in former centuries that of medicine would obviously make most appeal to the youth of scientific bent, and as L C Miall puts it in his book on "The Early Naturalists"

> "The medical school furnished the only regular training for the naturalist, whilst he found in the medical profession the likeliest means of earning his bread"

In his Rectorial Address to the University of Aberdeen, delivered in 1874, Huxley brought out the same point, with even wider application, when he said

> "Within my recollection, the only way in which a student could obtain anything like a training in physical science was by attending the lectures of professors of physical and natural science attached to the medical schools"

Still more striking is the following passage from the same address

> "In the days when all the innumerable applications of physical science to practical purposes were non-existent even in dreams, days which men living have heard their fathers speak of, what little physical science could be seen to bear *directly upon human life lay within the province of medicine* Medicine was the foster-mother of chemistry, because it had to do with the preparation of drugs and the detection of poisons of botany because it enabled the physician to recognize medicinal herbs, of comparative anatomy and physiology, because the man who studied human anatomy and physiology for purely practical purposes was led to extend his studies to the rest of the animal world"

Now that the practical applications of science are so far greater even than when these words were spoken, and a course of scientific training is necessary or desirable as a preparation for so many walks of life, there have sprung up schools of physical science of which the Royal School of Mines and the College of Chemistry, now fused into the Imperial College of Science, were the earliest to be established in this country Our universities also teach science in all its branches, and grant degrees therein In a word, science has been weaned from its foster-mother

Seeing, then, that in the past medicine has supplied opportunities of education for students of natural philosophy and natural history, and has, at the same time, supplied a stimulus to their researches, it need cause no surprise that our profession can claim, amongst its most honoured members, not a few whose work has inaugurated new epochs in widely diverse branches of natural knowledge

At first sight it would appear that astronomy, to which the natural approach is through mathematics, is as remote from medicine as any science can be, but there was a time when the pseudo-science of astrology supplied a close tie between the study of the stars and that of disease The mediaeval physician was profoundly influenced by the horoscope of his patient, and studied the motions and conjunctions of the planets to obtain such help in diagnosis and prognosis, as is afforded nowadays by the blood count or electro-cardiogram He was expected to have some knowledge of astrology, and even in the sixteenth century there were amongst our Fellows such men as Thomas Twyne (1543-1613), who gained more fame as an astrologer than as a physician, and some note as a poet In medical astronomers, on the other hand, have been [illegible] number, but Nicolas Copernicus (1473-1543), who revolutionized man's ideas of the universe, was a physician, and amongst lesser lights mention may be made of our Fellow John Bainbridge

Another science which has little contact with medicine is geology, save in so far as the nature of soils has bearings upon public health, but medical men have played very important parts in its advancement Thus, Nicholas Steensen, commonly called Steno (1638-1686), who discovered the parotid duct which bears his name, may be described as one of the founders of geology and mineralogy Most of his active life was spent in Florence, where he held the post of physician to two successive Grand Dukes Of him von Zittel wrote, in his History of Geology, that he was the first who sought to solve geological problems by inductive reasoning He threw much light upon the formation and structure of crystals, and, as Leonardo da Vinci had done a century and a half earlier, he maintained that fossils are the actual remains of animals and plants of former epochs He ended his life as a Catholic bishop and his ascetic habits undermined his health This brilliant Dane is entitled to rank amongst the great ones of science, as anatomist, geologist, mineralogist, and physician, but his researches, so far in advance of his time, only received their due recognition after much of his work had been done over again by later investigators

John Woodward (1665-1728), Professor of Medicine at Gresham College, and Fellow of this College, also holds a distinguished place in the annals of geology By his observations he acquired a most extensive knowledge of the structure of the earth's crust, and had learnt much as to the superposition of the various strata, but he propounded a fantastic hypothesis that the whole globe had been taken to pieces at Noah's flood, and that from the resulting "promiscuous mass" the various strata had been deposited in quick succession He bequeathed his collections to the University of Cambridge, where they form the nucleus of the museum which bears his name Woodward was less eminent as a physician than as a geologist, and was evidently a quarrelsome fellow, for he forfeited his Fellowship of the Royal Society because he insulted Sir Hans Sloane, to whom he refused to apologize, and a quarrel with Mead, over the treatment of small pox, led to a passage of arms, in which the sword of Mead but the tongue of Woodward gained the mastery "Take your life," said Mead "Anything but your physic," was the reply The celebrated James Hutton also (1726-1797), who propounded the rival and sounder theory that the moulding of the crust of the earth has been effected gradually, by processes such as are now at work, was a Doctor of Medicine of Leyden but soon abandoned the idea of medical practice

In more recent times the presidential chair of the Geological Society has been occupied by William Babington (1756-1833), physician to Guy's Hospital, and by John Whittaker Hulke (1830-1895), surgeon to the Middlesex Hospital, to whom that Society awarded the highest prize in its gift—the Wollaston medal, founded by our former Fellow, the distinguished chemist and mineralogist of that name

Physics and chemistry are the fundamental sciences upon which physiology and medicine rest, and throughout their history have been closely associated with medicine Galileo Galilei (1564-1642), equally pre-eminent as astronomer and physicist, was a student of medicine when he watched the swing of the lamp in Pisa Cathedral and so discovered the law of the pendulum It was by his pulse that he timed the swing, and the first use which he made of his discovery was to construct an instrument to measure the frequency of its beats The other outstanding physicist of the sixteenth century was a Fellow, and sometime President of this College, William Gilbert (1540-1603), founder of the science of magnetism, who recognized the earth's magnetic properties Of him Dryden wrote

> Gilbert shall live till loadstones cease to draw
> Or British fleets the boundless ocean awe

This College can also claim amongst its Fellows one of the most brilliant men of science whom our country has produced, Thomas Young (1773-1829) whose discoveries in optics, and especially that of the interference of light, went far to establish the undulatory theory He was the first to detect astigmatism, and threw much light upon the mechanism of the eye and on colour vision He was a great linguist also, and by his work on the Rosetta stone aided materially the interpretation of the demotic text thereof Yet he found time to hold the office of physician to St George's Hospital, and to practise medicine

Amongst other great medical physicists I may recall the name of Luigi Galvani (1737-1798), physician and anatomist, who was led to the discovery of current electricity by his investigations of the electric organs of certain fishes, William Charles Wells (1757-1817), who solved the problem of dew, Julius Mayer, physician of Heilbronn to whom is due some of the credit of the determination of the mechanical equivalent of heat, and, in our own time, Hermann von Helmholtz

There was a time toward the end of the seventeenth century, when a dominant position in medical thought was held by a group of so-called iatro-physicists, who influenced by the work of Galileo and his followers, and by the views on physiological problems of two great mathematicians—Descartes (1596-1650) and Borelli (1608-1679)—endeavoured, but with far less competence, to extend them to all physiological processes by the supposed action of forces upon particles of various shape and size Like the iatro-chemists whom they superseded they went too far had their day, and passed In the true line of succession from Borelli on the other hand was James Jurin (1684-1750) a Fellow of this College and physician to Guy's Hospital He was an eminent mathematician and physicist, whose aim it was to make physiology an exact science

With chemistry the links are even closer The alchemist, who sought to prepare the elixir of life, had kindred aims to those of the physician Later in the period of the iatro chemists—followers of Paracelsus, van Helmont and Sylvius—medicine was regarded as a mere branch of chemistry, and physiology as a form of fermentation—curiously like, and yet quite unlike the physiology of to-day A more practical tie between chemistry and medicine was provided by the chemical literature and the study of poisons

It was not until the seventeenth century that chemistry began to be studied as a pure science—in the days of Robert Boyle upon whom as an appropriate recognition Oxford bestowed the degree of Doctor of Medicine and another who, like him were actuated by a desire to learn of the nature and composition of things At Oxford the second holder of the short-lived Vinerian Professorship of Chemistry Edward Hannes (died 1710), was a physician, in the early years of the eighteenth century lectures on chemistry were given by John Freind (1675-1728), a Fellow of this College and Harveian Orator and by several other medical graduates and the first holder of the Aldrichian chair founded in 1803 was John Kidd, afterwards Regius Professor of Medicine

In the earlier days a knowledge of practical chemistry was only to be acquired by students in the shop of apothecaries and as a scientific training this is much to be desired It was Vauquelin (1763-1829) who first organized courses of instruction in his own laboratory in Paris and this method was followed by Thenard (1777-1857) and Gay Lussac (1763-1829) and greatly extended by Liebig (1803-1873) Ernst von Meyer tells that the laboratory of Thomas Thomson (1773-1852) a doctor of medicine of Edinburgh and professor of chemistry in Glasgow was the first to provide practical teaching in Great Britain and it was not until 1845 that the College of Chemistry was established in London, with A W Hofmann as its director

The list of physician chemists is a long one and only a few of the most eminent can be mentioned First may be recalled John Mayow (1643-1675) one of the greatest of them all Mayow stands high on the roll of physiologists as well as of chemists From the point which he reached only one step remained to the complete explanation of respiration and combustion, and but for his too early death the discovery of oxygen would almost certainly have been antedated by a century, and phlogiston would never have been heard of Although a doctor of civil law, Mayow practised medicine at Bath A contemporary of Mayow was our Fellow Thomas Willis (1621-1675), whose work upon the anatomy of the brain is commemorated by the circle

of arteries which bears his name But Willis was also no mean chemist, and to him we owe the discovery of glycosuria Mention must be made of Friedrich Hofmann of Halle (1660-1742), a contemporary of Boerhaave, and of the illustrious Herman Boerhaave (1668-1738) himself, whose treatise on chemistry was long the best textbook of the subject Yet eminent as Boerhaave was as a chemist, it was as a physician and professor of medicine that he was pre-eminent, and it was during his tenure of its chair of physic that Leyden, as a school of medicine, reached its zenith Cullen (1710-1790), Joseph Black (1728-1799) the discoverer of latent heat, and Wohler (1800-1882), who, by his synthesis of urea, bridged the imaginary gap between inorganic and organic compounds, were all members of our profession who made notable contributions to chemical knowledge It was a Professor of Medicine of Halle, Georg Ernst Stahl (1660-1734), who propounded the strange theory of phlogiston, which, like the old man of the sea, clung around the neck of chemistry and obsessed chemists for more than a century This hypothesis, which presented an inverted picture of the truth, like a glove *turned inside* out, was upheld by men of the highest ability, and by none more tenaciously than by such men as Priestley and Scheele, whose own researches were knocking away the props upon which it rested The great Swedish man of science, Berzelius (1779-1848), the foremost chemist of his time, and the inventor of our system of chemical symbols and formulæ, was a doctor, and for a time a professor, of medicine, and it was by his friend Alexander Marcet, a Fellow of this College, and one whose services to biochemistry are not sufficiently remembered, that Berzelius was led to illustrate his lectures by experiments

Two more physician chemists may complete our series—William Hyde Wollaston (1766-1828), a Fellow of this College, a most eminent man of science, whose contributions extend over physiology and pathology, mineralogy, optics, botany, and, above all, chemistry, and William Prout (1785-1850) *Wollaston discovered the malleability of platinum*, a property of great value to chemists and physicists alike, detected cystin in urinary calculi, and invented the camera lucida Prout was one of the founders of biochemistry, and discovered of the hydrochloric acid in the gastric juice His much discussed hypothesis, usually spoken of as "Prout's law," that the atomic weights of other elements are multiples of that of hydrogen, and that hydrogen is the basal substance from which all the other elements are formed, has long served as a potent stimulus to observation and research, and now, in a sense, is coming to its own

In these later days the ties between medicine and chemistry are being knit more closely than ever before Most drugs of recent introduction are, like aspirin, by-products of the gas-works or dye factory, or, like salvarsan and its allies, synthetic products of the laboratory But far more important to the progress of medical knowledge is the light which is being thrown, by the *rapid advance* of biochemistry, upon the problems of metabolism and chemical structure of the body

The history of other sciences tells a like story Almost all the early botanists were medical men, and the chief stimulus to the study of botany was the search for useful drugs This is true even of classical times, the days of Theophrastus and of Dioscorides The early scientists were with few exceptions, such as Archimedes, observers rather than experimenters, and the mere differentiation and naming of genera and species—a branch of science which dates back to the Garden of Eden, and of which that great naturalist, Linnaeus, was a brilliant exponent—afforded an immense field of work Of the *Materia Medica* of Dioscorides Charles Singer writes "Its history has shown it to be one of the most influential botanical treatises ever penned It provided most of the little botanical knowledge that reached the Middle Ages It furnished the chief stimulus to botanical research at the time of the Renaissance" In the fifteenth and following centuries a long line of medical botanists carried on the tradition, including Brunfels (1484-1534), Fuchs (1501-1566), Bock (1498-1554), and Gesner (1516-1565), the most learned naturalist of his century, botanist, zoologist, artist, and professor of Greek, who died of plague whilst faithfully carrying out his duty, as town physician at Zurich, during an epidemic of that malady

But to quote Miall once more "It was generally believed that for every ill that flesh is heir to, Nature had designated some plant as the appropriate cure", and again, "Some believed that Providence had created particular plants to grow in those districts where the diseases which they cure are prevalent" Can it be denied that such tenets are held by millions at the present day?

The high distinction of having initiated the study of vegetable anatomy and physiology, those higher branches of botany, is shared by two men of the seventeenth century, both of whom were physicians One of them, Nehemiah Grew (1641-1712), we may proudly claim as a Fellow of our College He it was who first recognized the sexes of plants and the functions of the stamens, but he himself gives some of the credit for this to our former President, Thomas Millington Of Grew, Hallam wrote that "no man, perhaps, who created a science has carried it farther," but he must share the renown with no less a colleague than Marcello Malpighi (1628-1694), in whose splendid record the study of plant anatomy takes but a minor place A professor of medicine, zoologist, and botanist, founder of the science of embryology, elucidator of the structure of the lung, spleen, and kidney, to Malpighi must be assigned very high rank amongst those who have contributed to the advancement of natural knowledge

On the other side, the greatest of systematic botanists, and founder of our system of nomenclature of plants and animals, Carl Linne, commonly called Linnæus (1707-1778), who has been *said to have* "found botany a chaos and left it a cosmos," was not only a doctor of medicine, but held the office of *physician to the Swedish navy*, and practised in Stockholm for a time

The ties between medicine and zoology are less obvious, for the search for animal drugs can hardly have led anyone to the study of natural history But the transition from human to comparative anatomy is easy, and there have been medical zoologists from early times In the sixteenth century we find the names of Rondelet (1507-1566), Belon (1517-1564), Conrad Gesner once more, and of our own former President Edward Wotton (1492-1555), whose work, *De Differentiis Animalium*, gained for him a European reputation, but is marked rather by erudition than by originality of outlook and observation In the seventeenth century there lived and worked Malpighi, whose chief contribution to zoology was a very complete study of the anatomy of the silkworm, Swammerdam (1637-1680), the Dutch microscopist who first observed the red corpuscles of the blood, and two Fellows of this College—Martin Lister (1638-1712), a man with wide interests and a special bent for the study of marine and freshwater molluscs, and Edward Tyson (1650-1708), the author of monographs upon the chimpanzee, porpoise, opossum, and rattlesnake, and who first described the patterns upon the finger-tips

In recent times we may claim Richard Owen (1804-1892), who was credited with the power of reconstructing an extinct monster from a single bone, and also one whose eloquent words still ring in the ears of some of us, the greatest of medical zoologists, Thomas Henry Huxley (1825-1895)

In reality, botany and zoology are far more closely allied to medicine than our fathers knew Since most maladies are due to invasion of the body by lowly organisms, some animal and some vegetable, we need to approach the study of disease from the standpoint of the invaders which are ever trying to gain a foothold, as well as from that of the tissues which present the role of a culture medium and offer all the resistance in their power In that struggle, which is waged with varying *fortunes*, we physicians are the allies of our patients, whose own tissues play the chief part in the defence In order that our aid should be as efficient as possible we need to know all that can be learned about the nature and habits of the invaders, and of the insects which are the other hosts of some of them, and the study of bacteria is a branch of botany, and that of protozoa of zoology

At the renascence of the medical sciences it was in human anatomy that the first advances were made, and the new anatomy was based upon dissection of the human body The pioneer of this advance was Andreas Vesalius (1514-1564) His work was carried on in Padua Others had dissected the human body before him, in Alexandria and at a later time in Bologna, but the prevalent teaching of anatomy followed the text of Galen, and was based, almost wholly, upon dissections of monkeys and lower animals From Vesalius dates the great period of the medical school of Padua during which there taught there, after Vesalius, Fallopius (1523-1562), Fabricius of Aquapendente (1537-1619), Casserius (1561-1616) and Spigelius (1578-1625)—men whose names are written large upon the organs and tissues of the body To Padua also, despite the difficulties, discomforts, and even dangers of travel in those times came students from afar, and amongst them our own Thomas Linacre John Caius, and William Harvey As Sir Clifford Allbutt justly said, in his notable Harveian Oration delivered a quarter of a century ago "It was in Padua that medicine, long degraded and disguised, was now to prove her lineage as the mother of natural science and the truth of the saying of Hippocrates, that to know the nature of man one must know the nature of all things"

It is not necessary that I should dwell upon the share of medical men in the building up of modern physiology, for from Harvey onwards it has been almost entirely their work, but the day has passed in which physiology was regarded as the handmaid of medicine, and it has taken its proper place as a great independent science

Morbid anatomy, as an adjunct to clinical medicine dates back to the illustrious Morgagni (1682 1772), and so to Padua once more, and is intimately associated with the other great names of Albert von Haller (1708-1777) and Rudolph Virchow Knowledge of the changes, both great and minute, wrought by disease in the organs and tissues is still as essential as ever in the training of the physician and surgeon but morbid anatomy is no longer coextensive with pathology, and the pathology of to-day has entered upon entirely new fields So, as we well know modern pathology has rendered possible the destruction of the agents of disease or of their insect hosts before they reach the body—the triumphant achievements of preventive medicine Moreover, as the result of the study of immunity the bacteriologist is teaching us how to apply Nature's own selective remedies in place of the cruder drugs of earlier days At the same time, the pharmacologists are bringing to the test of scientific method the actions and uses of drugs which have long been used in an empirical way and are able to explain the proved utility of some which owe their introduction into the pharmacopoeia to superstition, or to some grotesque hypothesis

So, from the foundations of chemistry physics and biology, through the lower stories of human anatomy and physiology, of pathology and pharmacology we reach the cities once more, and come back to Hippocrates, to the bedside examination of the sick and injured But now that the foundations have been well and truly laid the clinical medicine of to-day is able to advance on scientific lines and the study of the abnormal can be based upon a knowledge of the normal

All who have taken part in this work, all those heroes of science and medicine whose names have been mentioned may rank as benefactors of this College both those who were its Fellows and those who were not and in commemorating them I may claim to have followed Harvey's first injunction

It is natural, nay inevitable, that as medical science grows and advances some of the workers in the field should elect to follow the path which leads through the laboratory whereas to others the wards make a stronger appeal and thus is taking place a differentiation of medical workers into distinct groups, and there is danger that the fission may go too far The worker in the laboratory wedded to his more exact methods, and distrustful of those with which the clinician is often compelled to be content, is apt to place his bedside colleague in a lower grade of caste than his own He is apt to look too much at the disease and too little at the patient, and to forget how greatly the former is shaped by the reactions and idiosyncrasies of the latter

We all know that a line of treatment resting upon a strictly rational basis may be useless or even harmful in an individual case It would be nothing short of a calamity were all the best scientific workers who enter our profession to be diverted from its clinical side to laboratory investigation for of no walk of life is it more true than of the practice of our art that "the multitude of the wise is the welfare of the world" From the ranks of the clinical workers have been drawn those who in the past have built up medical science It was in the intervals of their clinical practice that such men as Harvey himself William Gilbert, Nehemiah Grew and Thomas Young carried out the researches which have made them for ever famous, and, indeed, clinical medicine is itself essentially scientific

But clinical medicine is an art as well as a science and in the sick room many qualities are called for which are not essential in the laboratory A man who is deeply imbued with the spirit of science may prove a very poor practitioner whereas another, rich in common sense sound knowledge experience, and human sympathy, but to whom abstract science makes little appeal may make a very good one Tact and equanimity courage and restraint patience with fads and sympathy with grief diagnostic skill and manual dexterity are qualities called for in the daily work of the practitioner of medicine or surgery The marvel is that on the scientific side he has accomplished so much not that he has failed to accomplish more It ill becomes his colleagues in the laboratory to think slightingly of him

Medicine indeed embraces a number of constituent sciences and for the attainment of her benefactor aims all her branches need to work together in mutual respect amity and concord to bear in mind Harvey's third injunction to that effect, and his reminder that 'Concordia res parvæ crescunt, discordia magnæ dilabuntur"

Not only are the diagnostic methods which we employ in accord with the demands of science but also by the bedside study of signs and symptoms, and the recognition of the morbid anatomical changes with which they are associated, and also by the observation of the effects of surgical removal or gunshot injury of parts, very notable contributions to physiology have been made

Consider for a moment how our knowledge of the functions of the endocrine glands has been obtained The acumen and care in observation of that splendid clinician Addison threw the first ray of light upon the subject and removed the adrenal glands from the realm of mystery into that of observed fact The gradual accumulation of facts concerning exophthalmic goitre Gull's discovery of myxœdema, Kocher's observations upon cachexia strumipriva, and the effects of thyroid treatment provide a connected story of clinical work in medicine and surgery which led up to a solution of the functions of the thyroid gland and which had its practical outcome in the restoration to health of many sufferers from myxœdema the rescue of many cretins from imbecility and arrest of growth, and the amelioration of the lot of many sufferers from Graves's disease Again, it was the recognition of acromegaly by Pierre Marie, the study of its symptoms and morbid anatomy, the recognition by Erdheim of the syndrome which bears his name and that of the other results of pituitary defect together with the surgical results of Cushing and others which led us to our knowledge of the functions of the hypophysis knowledge which has been greatly extended by the experimental work of Schafer Moreover the inkling we have of the functions of the pineal gland and of the adrenal cortex are mainly derived from clinical observations of patients with tumour or other structural

The chance that an accidental gunshot wound led the French Canadian Alexis St Martin with a gastric fistula, and that the American army surgeon Beaumont under whose care he came, was able to take full advantage of the opportunity so afforded of studying the secretion and action

of the gastric juice, proved of the utmost value in the elucidation of the problems of digestion And in these times many clinical devices, such as test meals, duodenal soundings, and bismuth meals, are throwing yet further light upon physiological as well as pathological processes

The knowledge acquired in recent years of the mechanism of the heart's action is a triumph of scientific clinical medicine This work, which is so closely associated with the names of James Mackenzie, Thomas Lewis, Wenckebach, and Einthoven, has been gained mainly by the study of derangements of the heart's beat in man, by means of the polygraph and electro-cardiograph

But perhaps the most striking examples of all are afforded by the work which has been done upon the nervous system Bouillaud described clinical and pathological physiology as the sister of experimental physiology, and since the middle of the nineteenth century an immense amount of knowledge of the functions of the brain and spinal cord has been acquired by the labours of a band of brilliant investigators, many of whom are our own countrymen, and most were, or are, physicians or surgeons Of these I may mention Hughlings Jackson and David Ferrier, Charles Beevor, Victor Horsley, and Henry Head in this country, and on the Continent, Hitzig, Erb, Westphal, and Pierre Marie By their researches they have furthered the work of the pure physiologists, Sherrington, Gaskell, Langley, Gotch, and others

As regards localization, the first definite steps indicating that the brain does not function as a whole, but as a congeries of organs, was the localization by Broca of the motor speech centre, in 1861, which was based upon the position of the local lesions in fatal cases of aphasia, and Hughlings Jackson's study of convulsions due to cortical lesions These observations served as stimuli and pointed a way which was followed by many other observers, but by a not unfamiliar irony of things the assignment of a speech centre to the convolution of Broca no longer meets with acceptance

Lastly may be cited the work of Head upon the seats of pain due to visceral lesions, and upon epicritic and protopathic sensations It is clear that clinical observation is the royal road to the study of many kinds of sensory disturbance, in which an intelligent subject who can describe his sensations is needed, and in some instances the investigators have controlled their clinical observations by experiments upon themselves

The examples quoted show that, apart from the study of disease in bulk, and by statistical methods, there is also much to be learnt from the detailed study of individual cases

In a letter which Harvey wrote only six weeks before his death, to a Dutch physician who had sent him an unusual specimen, occurs the following passage "It is even so —Nature is nowhere accustomed more openly to display her secret mysteries than in cases where she shows traces of her workings apart from the beaten path, nor is there any better way to advance the proper practice of medicine than to give our minds to the discovery of the usual law of Nature, by careful investigation of cases of rarer forms of disease For it has been found, in almost all things, that what they contain of useful or applicable is hardly perceived unless we are deprived of them, or they become deranged in some way"

These words, as true to-day as when they were written are full of encouragement for those of us for whom the study of Nature's experiments and mistakes has a special attraction The structural malformation, or the hereditary and inborn departure from the normal of metabolism, although unimportant from the practical standpoint, may throw a ray of light into some dark place of embryology or biochemistry, and not a few of the rare maladies, such as chloroma, polycythæmia vera, sulphæmoglobinæmia, and the disease of which Bence-Jones albuminuria is a sign, offer fascinating and still unsolved problems of physiology and pathology

Obviously clinical medicine presents immense fields of scientific research, and those who cultivate them have the added satisfaction of knowing that every advance of medical science will, sooner or later, bring in its train some forward movement of the healing art

So, as we trace the history of natural science down through the centuries, we are confronted at every stage by the influence of medicine upon its progress The desire to alleviate human suffering, to repair the ravages of disease, and to mend the broken part, has served as a powerful stimulus to observation and experimental work It soon became obvious to the would-be healers that to understand disease they must needs understand the healthy workings of the organism and that pure science must precede applied So, as Huxley said, medicine became the foster-mother of the sciences But she became their school mistress also, and attracted to herself men whose scientific abilities would hardly have found an outlet in the other walks of life open to them in the earlier days, and them she not only taught but supplied with means of livelihood whilst they pursued their chosen studies Her part was rather that of a mother than of a foster-mother They, in their turn, repaid her care by laying firm foundations upon which a rational healing art could be built up, and, as we have seen, not a few of them achieved epoch making results in sciences outside the range of medicine

Thus it has come about that immense, and indeed incalculable, as is the debt of medicine to the pure sciences, the debt of science to medicine is hardly if at all less great But these mutual obligations are but internal debts, and the fact that medicine, in its widest sense, is merely a branch of natural science was recognized even by Aristotle, who, at the end of his work on respiration, wrote as follows

> "Our discussion of life and death and kindred topics is now practically complete But health and disease also claim the attention of the scientist and not merely the physician, in so far as an account of their causes is concerned The extent to which these two differ, and investigate diverse provinces must not escape us, since facts show that their inquiries are to a certain extent at least, conterminous For physicians of culture and refinement make some mention of natural science and claim to derive their principles from it, while the most accomplished investigators into nature generally push their studies so far as to conclude with an account of medical principles"

Yet, as Huxley pointed out, "It is a peculiarity of the physical sciences that they are independent in proportion as they are imperfect, and it is only as they advance that the bonds which unite them become apparent" That this is so is far more obvious to-day than when these words were spoken more than forty years ago For as we gain more knowledge innumerable fresh links are brought to light, and the unity of natural science is daily being revealed more clearly as the boundaries of its several branches fade and become indistinct

Few will any longer question the view that physiology is merely the chemistry and physics of living things Physics has captured the structure of the atom, is absorbing chemistry into itself, and is becoming revealed as the great fundamental science, of which all the others are but branches In this great complex of interlocked studies those which we class together under the comprehensive name of medicine have their allotted places, and advance in any one branch forwards the progress of the whole To take our part in this progress is alike our privilege and our obligation as members of the great band of seekers after natural knowledge

Upon the ceiling of the cloister of the University of Padua there are painted "stemmata" which record the sojourn there of many students who were councillors of their several "Nations," and amongst them are two which bear the name of Gulielmus Harveus, Anglus Some of the designs are heraldic, but Harvey's is symbolic, and prophetic I might add, in which, in place of a lifeless staff, the twin serpents are entwined round a lighted candle which throws out beams in all directions What more fitting emblem could have been devised? And yet these stemmata were painted when Harvey's work was scarce begun, and when he was still a member of the student body To search and study out the secrets of Nature by way of experiment" was his own way of life, and it is my duty to obey his injunction, and to exhort our younger brethren in the College to tread the path in which he led the way, and to see to it that in their hands the flame which Harvey lit shall burn as brightly as in Harvey's day

FOUR CASES OF EXOPHTHALMIC GOITRE TREATED WITH INSULIN

A Preliminary Report to the Medical Research Council

BY

R. D. LAWRENCE, M.A., M.D. ABERD.,

CHEMICAL PATHOLOGIST KING'S COLLEGE HOSPITAL

THE idea of treating hyperthyroidism with insulin was founded on the hypothesis of an antagonism between the hormones of the thyroid and the pancreas. Such an hypothesis admits of no definite proof, but the pathological and experimental evidence in its favour seemed to warrant the hope that insulin might prove useful in the treatment of hyperthyroidism and exophthalmic goitre. Since this work was begun, Goffin[1] has published a report of four cases of Graves's disease treated with insulin, three of which were greatly ameliorated. His work may be criticized on the grounds that no estimations of basal metabolism were made and therefore hyperthyroidism was not definitely established, nor is there a record of the conditions of his experiment being carefully controlled. Of the four cases here reported two were successful, and though it is too early to generalize on these few cases, they seem to give an indication of the type of case most likely to benefit from insulin. As each case requires very thorough and prolonged investigation to be of real experimental value and few can be adequately undertaken at a time, the following four cases are recorded now in detail in the hope that others may be tempted to investigate the question.

Evidence of an Antagonism between the Thyroid and the Pancreas

The clinical picture of hyperthyroidism and exophthalmic goitre is well known. The condition is due to an increased production and perhaps a qualitative change in the specific hormone thyroxin, an iodine compound. When this is present in excess, as in exophthalmic goitre, the metabolism as judged by the minimal heat production—the basal metabolic rate as it is called—is markedly increased, katabolism exceeds anabolism, the tissues are rapidly broken down and nitrogenous excretion is increased, weight is lost, the pulse and respiration are rapid, and the temperature often elevated. In brief, thyroxin acts as an excessive draught to the fires of the body. In addition the sympathetic system is over active, and to this the symptoms of nervousness, tremors, and exophthalmos are commonly ascribed. The carbohydrate metabolism is frequently upset and spontaneous glycosuria and hyperglycaemia may occur. More often this appears only on a glucose tolerance test, which shows a high and prolonged blood sugar curve. Usually the fasting blood sugar is normal, and it would seem that the oxidation of carbohydrates is normal and only the glycogenic function of the liver defective at first. This may lead subsequently to a true diabetes mellitus, presumably by prolonged overstrain of the pancreas.

On the other hand, although we do not know of any condition of excessive production of insulin by the body (hyperinsulinism), the effects of insulin are the opposite of thyroxin in several directions. Its total effect on metabolism apart from diabetes is little known, but it would appear to retard metabolism especially when the blood sugar is reduced to a low level (Macleod, 1924). Its effect on the weight of non diabetics is also unknown, although Harrison[2] has failed to fatten rabbits on large doses of insulin. But Garrelon and Santenoise[4] have recently shown its action as a vagotonic agent, apart from its hypoglycaemic effect, but owing to the importance of its therapeutic possibilities this point requires confirmation. Certainly some of the early symptoms of hypoglycaemia—the hunger pains, the occasional colic, and the heavy slow palpitation—are suggestive of parasympathetic vagus stimulation, the opposite of the sympathetic effect of hyperthyroidism. Insulin reduces the blood sugar and undoubtedly restores the glycogenic function, of the liver or a diabetic, or at least enables it to store glycogen. Loewi's adrenaline eye test for dilatation of the pupil may be cited as further evidence, for in Graves's disease it is often positive from increased sympathetic tone and in diabetes (hypoinsulinism) often positive from failure of the pancreatic hormone to counterbalance the sympathetic tonus—or so the theory goes.

Some experimental work on animals is definite in support of a thyroid insulin antagonism. Duchêneau[5] showed that thyroidectomy makes rabbits more sensitive to insulin. Burn and Marks confirmed this, and went further by showing that thyroid feeding makes a thyroidectomized rabbit again more insensitive to insulin. Falta states that—

> extirpation of the thyroid raises the assimilation limits for carbohydrates and reduces the protein metabolism during fasting. Extirpation of the pancreas reduces the assimilation limit for strongly and increases the protein metabolism during fasting. Simultaneous extirpation of the thyroid and pancreas produces indeed a diabetes this however pursues a milder course to the extent that the increase of the protein destruction is not so high and the diminution in weight does not increase so rapidly.

Friedman and Gottesman[3] have recently confirmed this. There is thus much scattered evidence to suggest a correlation between the thyroid and the pancreas, but so far most tends to show that the thyroid is an antagonist to insulin than the other way about.

Plan of Author's Investigation

Spontaneous variations in the clinical condition of a case of Graves's disease are notorious, and the consequent difficulty in estimating the specific effect of any treatment is recognized. In this investigation care has been taken to allow time for the preliminary improvement that rest in hospital usually brings about before starting insulin treatment. The patients were placed on a fixed diet to avoid changes in weight and metabolism due to diet alone, and to make it safe to give large doses of insulin with blood sugar control. Improvement was to be judged by changes in the general condition of the patient, the size of the thyroid, the nervous symptoms, the weight, and the pulse rate, and most important of all the basal metabolic rate. It was intended to estimate the nitrogenous excretion also, but so far this has not been done. All the patients were confined to bed throughout the investigation, and indeed were too ill to be allowed up. The progress of the cases is recorded in the tables which show the weekly change in weight morning and evening, pulse rate, basal metabolic rate, the units of insulin per day, and the respiratory quotient. The modified Thorn sphygmometer was used for the basal, supplied by the Sanborn Company, was used for the basal metabolic estimations, and the air analysed in a Haldane's apparatus. The tests were carried out in normal fasting hours after the last meal although a cup of tea was allowed four hours before the test for the comfort of the patient and seemed to make no difference. As all the patients presented ocular and nervous symptoms, tremor, tachycardia, and dilatation of the heart and enlarged thyroid these are not mentioned again in detail unless of special interest.

CASE I

An unmarried woman aged 23 was admitted to hospital on April 23rd with a history of feeling ill for three months, which had rapidly enlarged and begun to cause trouble during the last six months. She presented all the cardinal symptoms of exophthalmic goitre, the right lobe was more enlarged than the left and caused deviation of the trachea and dysphagia. The apex beat was 4½ in. from the mid-sternal line, and the case was too bad under medical treatment, and in Dr. Fraser's opinion was too bad for a surgical risk for operation. I was asked to take this opportunity of expressing my indebtedness to him for his kindness and especially for help in the examination of the heart. She had no glycosuria and no other symptoms pointing to hyperglycaemia.

Before starting insulin her average [illegible] was 1 [illegible] days and estimated at 500 grams of carbohydrate + 120 grams protein and 150 grams of fat. She was [illegible] on a diet arranged in our measures as near that as could be [illegible] kilogram of body weight and [illegible] 1,500 calories a day before operation and tea. Her progress [illegible] Table I. I do not think that [illegible] the insulin has to be increased [illegible] the injections

injections before and hardly knew they were changed Yet even after four days of insulin she was positive that the neck was less tense and that she could swallow better The insulin was increased in ten days up to 90 units, and four days later she had mild symptoms of hypoglycaemia (blood sugar 0 069 per cent) coinciding with the use of a new batch of insulin The dose was subsequently dropped to 80 units, which caused no inconvenience either locally or generally

At the end of three weeks the tremors and exophthalmos were quite gone and she felt much better and walked better The basal metabolism had dropped, but the pulse rate took longer to follow suit As she felt very hungry (an insulin effect) her diet was raised at the fourth week by 100 grams, after which she increased much more rapidly in weight Her general improvement was marvellous, insulin was discontinued after nine weeks, but her progress was still maintained, and all this during the hottest period of the summer, which is often fatal to these cases The thyroid obviously diminished in tenseness and size, but the measurements were unfortunately not made by the same person throughout the investigation and vary too much to afford any real indication As her weight increased the added fat tended to mask any diminution in the size of the gland, but at the end of her treatment it was still slightly enlarged The heart had returned to the normal position, and the pulse rate remained steady during the last fortnight, when she was allowed to walk about the ward

TABLE I

Weeks *	Weight in lb	Pulse		Basal Metabolic Rate per Cent	Respiratory Quotient	Insulin Units per Day

* Weeks before and after insulin treatment Insulin commenced at 0 This applies to the four tables

CASE II

A married woman, aged 28 was admitted to hospital with a history of swelling in the neck for six months and exophthalmos and extreme nervousness since a miscarriage three months ago The Wassermann reaction was negative She was excessively nervous and restless on admission and the heart was slightly dilated She had glycosuria (2 per cent in the twenty four hour urine), normal fasting blood sugar but hyperglycaemia after meals The variations in the carbohydrate metabolism throughout the experiment are very interesting

After two weeks of rest her basal metabolic rate had become stable, and she was put on a diet of 350 grams of carbohydrate, 120 grams of protein, 150 grams of fat, and 40 units of insulin given in two doses She became sugar free in three days and developed an enormous appetite an effect which insulin produced on three of the four cases Instead of losing weight she gained a pound in the first four days Accordingly 100 grams of carbohydrate were added to her diet in the form of bread and the insulin raised gradually to 100 units a day At the end of the second week she had greatly improved, she had gained 5 lb and the pulse and basal metabolic rates were dropping The fasting blood sugar was normal, and five and a half hours after the morning dose of 50 units was 0 074 per cent She never had any hypoglycaemic symptoms except that she was always very hungry even after a large meal I had now got her into the state at which I was aiming in which I hoped insulin would have its maximal beneficial effect either by the low blood sugars *per se*, by a direct antagonism to an excess of thyroxin, or by its general restraining influence on metabolism It seemed to be having the desired effect but she then received some very worrying domestic news which upset her completely, and she relapsed in every way except that she still continued to gain weight She was kept on the same diet and in spite of 100 units of insulin a day began to pass much sugar in the fourth week, and by the end of the fifth week the blood sugar was 0 179 per cent fasting level and 0 372 per cent two hours after dinner—figures which showed that the condition of the carbohydrate metabolism had become typical of diabetes rather than of hyperthyroidism The interesting question arises whether this was caused by the mental upset by an increased secretion of thyroxin rendering the insulin ineffectual, or by a diminished tolerance accompanying the rise in weight, or by a combination of these factors The carbohydrates were reduced to 350 grams a day in the fifth week, to 250 grams in the sixth and 200 in the seventh week, but in spite of the large dose of 100 units insulin a day, it was not till the eighth week that she became sugar free with normal blood sugars Her source of worry was removed in the sixth week, and after this she rapidly improved and felt so well that she decided to go home In spite of a diet ample in bulk and calories she complained of always feeling hungry, even when the blood sugar estimates were high, an effect probably due to insulin apart from the blood sugar level and noticeable in many diabetics under insulin This, I would suggest, is a vagotonic effect It is interesting to note that insulin raised the respiratory quotient markedly except in the fifth week, when the blood sugars showed her to be in a diabetic condition She never showed any ketosis

On discharge from hospital she declared herself better than she had been for months Her muscular power had greatly improved and the tremors almost disappeared The exophthalmos and the pulse rate were only slightly diminished The circumference of the neck diminished one inch in spite of the fact that the weight increased 26 lb The change in size and pulsation was most noticeable in the left lobe, but there was no sign of any residual adenoma in the right lobe to account for the fact that it hardly diminished at all

The insulin was suddenly discontinued during the last three days as the patient was anxious to leave, and slight glycosuria reappeared It is hoped to continue the investigation of this patient as soon as she can be readmitted to hospital

TABLE II

Weeks	Weight in lb	Pulse		Basal Metabolic Rate per Cent	Respiratory Quotient	Insulin Units per Day

8	105	100	120	+24	0 82	100

CASE III

A married woman, aged 50, a severe case with marked tremor and muscular weakness was admitted with a history of swelling in the neck, nervousness, and palpation for two years and exophthalmos for sixteen months A carcinoma of the right breast had been removed four years previously and showed no sign of recurrence A deep seated adenoma could be felt in the right lobe,

TABLE III

Weeks	Weight in lb	Pulse		Basal Metabolic Rate per Cent	Respiratory Quotient	Insulin Units per Day
		Morning	Evening			
2	92	96	104	—	—	0
1	90	100	100	+42	0 77	0
0	89	96	100	+39	0 81	40 to 50
1	92	96	100	—	—	60 to 70

6	105	83	120	—	—	90
7	105	84	108	+46	0 77	90
8	105	88	112	+40	0 76	0

which was larger than the left. She had transient glycosuria on normal fasting blood sugar but gave a typical prolonged curve of slight hyperglycaemia with 50 grams of glucose.

Insulin was commenced with 40 units on a diet of 450 grams of carbohydrate, 120 grams of protein and 150 grams of fat—somewhat higher than she had been eating before. At first this proved too much for her but her appetite improved as the insulin was increased to 80 units and she rapidly gained in weight. She did not improve in other respects and after a month the insulin was reduced to 20 units a day. On this the gain in weight was not maintained, perhaps partly because appetite diminished although she was still able to eat a very liberal diet. When insulin was discontinued her general condition was little if at all improved although the tremors were appreciably less. The neck measurement remained unchanged but it must be remembered that she had gained 14 lb. to offset this. The *left lobe* was decidedly diminished and the adenoma in the right lobe was more obvious as the remainder of the lobe seemed to have shrunk. After the insulin was reduced below 40 units she ceased to gain weight but had no recurrence of glycosuria. The pulse and basal metabolic rate fell somewhat probably because she began to sleep better under the influence of bromides.

CASE IV

A married woman aged 47 was admitted on May 28th with a history of dysphagia for eighteen months and noticeable thyroid enlargement and exophthalmos for twelve months. She presented all the symptoms of Graves's disease and a dilated heart was found but from the presence of several nodules in the thyroid she was rather a case of toxic adenoma than of simple exophthalmic goitre. Glycosuria and hyperglycaemia were absent. The Wassermann reaction was weakly positive but this is common in hyperthyroidism and no significance was attached to it.

She was treated with x rays for a month with *no benefit* except that the thyroid became harder. She continued to lose weight as shown in the table. Accordingly she was put on a diet of *350 grams of carbohydrate 120 gram of protein and 150 grams* of fat—approximately what she was eating at the time—and 80 units and later 60 units of insulin were given. She got worse and developed pressure symptoms on the trachea so that the insulin was discontinued after a month. Unlike the other three cases she did not even gain weight appreciably although the loss was checked for a time.

TABLE IV

The possible mode of action of insulin in hyperthyroidism whether by direct chemical or physiological antagonism by primary effect on carbohydrate metabolism or as a vagotonic with a general anabolic action will be discussed in a later publication when more evidence including some animal experiments, has accumulated. But it already seems possible to correlate the results in these four cases with different types of hyperthyroidism. Two cases were successful one strikingly so, and these were uncomplicated though severe cases of Graves's disease in young women. In one the carbohydrate metabolism was never abnormal so that insulin did not act primarily by correcting this. The two unsuccessful cases were older women and the disease of longer standing. One of them Case III was definitely a toxic adenoma (Graves's syndrome associated with adenoma of the thyroid), and though he gained in weight and felt better she did not fundamentally improve. Case IV, a complete failure, was admitted as a case of toxic adenoma but *when I examined her after the thyroid had* become hard, following a course of x rays I could not be sure of this. Therefore it would appear that hyperthyroidism arising from an adenomatous condition of the thyroid is not likely to benefit from insulin, and that the most hopeful are simple cases of Graves's disease. Indeed, on *a priori* grounds we could hardly expect insulin to influence an adenomatous condition or the thyroid to which the general metabolic disturbance seems to be secondary.

Nothing definite can be said regarding the dose of insulin. On theoretical grounds big doses would seem more likely to succeed and certainly small doses were no more effective than large. In Case III Griffin however reports improvement in his cases with 10 units a day and never gave more than 20.

The rise in the respiratory quotient under insulin was marked in the two successful cases but indifferent or absent in the failures. Such a rise may prove to indicate those for whom the treatment is likely to be successful in any case. It can hardly be due to the direct action of additional circulating insulin as the estimations were made eight hours after the last dose of insulin. It would seem to *indicate a* check on the former excessive katabolism of protein accompanied by improved glycogenic function of the liver or at least a storage of carbohydrate under the influence of insulin which remains available for oxidation even when the insulin effect wears off as occurs in diabetes.

The gain in weight was striking in three of the cases and in the first two was not due to any change in diet because they were kept on the same diet before and after the commencement of insulin and the gain in weight was evident before the diet was increased in response to the appetite *created by insulin. This suggests the use of insulin* in the treatment of undernutrition and emaciation in cases other than diabetes and hyperthyroidism. It is probable that insulin will acquire a much wider therapeutic field with the progress of time.

SUMMARY

1 Four severe cases of Graves's disease with hyperthyroidism were treated with large doses of insulin 60 to 100 units a day. The insulin was well borne and caused no inconvenience.

2 Two of the cases were greatly improved *one being* practically normal on discharge from hospital. In both the disease was uncomplicated and of less than a year's duration in women under 30. It seems unlikely that the *improvement was spontaneous or caused by any factor* other than insulin.

3 The two others were not essentially benefited although one gained much in weight and felt better. These were cases of toxic adenoma of the thyroid rather than of simple Graves's disease occurring in women of about 50 and of over a year's duration.

4 The treatment was carried on under strict standardised condition of diet and close blood sugar control but should its value become established these should hardly be necessary.

5 The subject is still in its experimental stage and these four cases are recorded now mainly in the hope that other workers may investigate its possibilities.

I wish to thank the physicians of King's College Hospital for permission to observe these cases the sister for her careful dietetic control the house-physician for their close co-operation and Mr. L. Hewer for many of the blood sugar estimations.

DISCUSSION ON THE MICROSCOPY OF THE LIVING EYE.

OPENING PAPERS

I.—BASIL GRAVES, *M C*,

Curator, the Royal Westminster Ophthalmic Hospital, British Medical Association Science Research Scholar

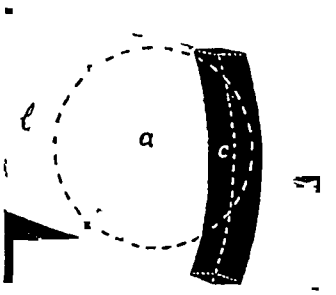
THE PHYSIOLOGICAL ASPECT

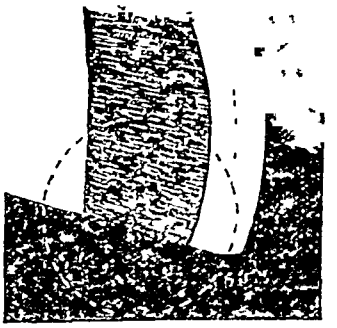
It gives me great pleasure that I have been asked to contribute to the opening of this discussion The restricting of my contribution to the subject of the living eyes which are normal has, however, rather taxed me to present to you, in the short time available, an aspect of the subject which shall be both concise and interesting A full understanding of the normal effects is certainly a very necessary basis for the appreciation of what is pathological, but to summarize the various features seen in the different regions, from cornea and sclera right back to the retina and optic disc, would not be possible now, nor do I want to attempt it, because by now many of these features have come to be commonplace

The comprehension of the diverse features met with in the microscopy of both normal and pathological living eyes reverts always to a proper understanding of principles of illumination, with particular reference to the subject of optical sections, using this term in its widest sense At the annual congress of the Ophthalmological Society of the United Kingdom in Glasgow last May I brought forward certain clinical points in connexion with the optical section in the normal cornea I propose now to take this opportunity to present only two features—one relating to the optical section of the normal aqueous fluid, the other to the optical section of the normal lens—to which, as far as I am aware, attention has not yet been drawn

It is customary to regard the normal aqueous fluid as being non-relucent That this is not so I think it will be possible, to-morrow, to demonstrate practically to those to whom it may be of interest Mr J E Barnard, F R S, for the assistance of whose opinions I have had occasion to be much indebted, tells me that he would not expect any body fluid to be optically empty, even the cerebro-spinal fluid is not so Now I do not raise this point as a mere quibble, it is in my opinion a rather important point to recognize in the practical technique of this work—one which, as the cumulative evidence of various trained observers comes to hand, will possibly have an interesting clinical significance in relation to some varieties of intra-ocular disease

Owing to the reluctancy of the cornea and lens, the visibility of the ribbon-like slit-beam, as it traverses these two structures, is relatively high Between the planes of its passage through these the path of the beam, through the intervening normal aqueous fluid, is generally said not to be visible, this teaching arises from lack of suitable use of the facilities at our disposal The normal aqueous fluid, though admittedly only very slightly so, is reluctant If the beam is to be seen traversing the normal aqueous fluid it is necessary that the field of observation shall include both an area of the fluid which is transmitting the beam, and, for contrast, above and below this, an area of fluid which is unilluminated by the passage of the beam The observation of an area of the aqueous fluid so illuminated by the ribbon-like beam that it more than covers the diameter of the field of observation, does not permit of visibility of the beam when the fluid is normal (See Fig 1, in which *c* represents cornea, *a* aqueous, *l* lens, and the dotted circle the limit of the field of observation) Only when this fluid is very abnormal, so that from gross alteration of its colloid physical and chemical constituents it becomes relatively highly reluctant can the passage of the beam be appreciated under these conditions of observation, and such pathological pictures as that of Fig 2* are already forthcoming commonly in





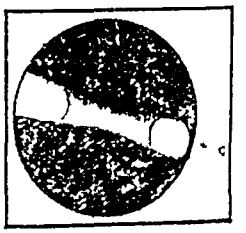


Fig 1

Fig 2

relation to uveitis in its severe—for example, sympathizing—forms

To make the optical loading of the aqueous fluid more readily appreciable in its earlier and finer pathological stages the field of observation may be arranged according to the plan of Fig 3, where the fluid is illuminated in one half—top or bottom—of the visual field, whilst no light is being transmitted in the fluid occupying the remaining half of the field Now from the contrast thus afforded pathological reluctancy of the aqueous fluid will be appreciated in finer degrees than is possible under the conditions of illumination of Fig 1, but even so, very fine degrees of increased reluctancy will not be appreciated thus, for more than one reason first, a relatively large area of cornea and of, say, lens within the visual field is brightly illuminated, and this tends to impair the observer's dark adaptation so necessary for his recognition of very fine contrasts, secondly, it is possible that the total amount of light thrown into the observed eye, when the slit-beam is used, is such that the amount of reflection, diffuse or otherwise, taking place from the medium, be it iris or lens, behind the aqueous fluid, to some extent causes an illumination of that part of the fluid which is not transmitting the entering beam I then made observations on the

Fig 3

Fig 4

aqueous fluid by cutting down the vertical diameter of the slit-beam to a very small length, and finally I came to use a round beam of very small diameter This is attained, when the ordinary pattern of the Zeiss make of nitra slit-lamp is used, by means of either the 0 5 or the 1 0 mm dot diaphragm With the arc slit-lamp it is generally preferable to use the smaller of these two dot-apertures

Now, using the ordinary nitra slit-lamp and the 1 mm dot-aperture, the observer may see, as shown diagrammatically in Fig 4,† the path of the beam traversing the normal aqueous fluid if he attends to these points, some of which are better demonstrated than described It is of which are better demonstrated than described It is of that the filament of the nitra-lamp should be loaded to the maximum of its current-capacity, this generally not

* The long faint streaks in the beam represent shadow streaks which were due to irregularities of surface contour caused by the presentation of a mydriatic in thick oily solution

† In Fig 4 the visibility of the aqueous beam is exaggerated

sita es alterin_ the set stop, inside the adjustable resistance, from the position it is in when sent out by the makers Only a few seconds are necessary for the observer s dark-adaptation, but the room should be really dark The observer should choose an angle of illumination which will not allow the specular reflection from the corneal epithelium to strike the microscope objective lenses, even though the reflected beam is not so directed as to pass along the axis of either of the objective tubes the beam should be accurately focused in the middle depth of the aqueous fluid — that is midway between cornea and anterior lens capsule the beam having traversed the aqueous fluid, should not strike the iris—a not uncommon error which gives rise to much diffuse reflection within the anterior chamber—but should pass on through the pupil into the lens, for which reason it is easier to observe the relucency of the normal aqueous fluid when the pupil of the observed eye is dilated The observer, using preferably oculars No 2 and objective a2, should see the small round corneal beam just on the one side of his chosen field and the beam as it enters the lens on the other side, the illumination being focused midway between these two levels, he will then bring the microscope to a focus on the illuminated aqueous fluid by first focusing on the illuminated corneal patch or on the illuminated anterior lens-capsule, then deliberately racking the microscope a little forwards or backwards as the case may be, to an extent which is really only guessed at out which becomes automatically accurate with practice The necessary adjustments thus being made, the observer need attend to only one or two points in order easily to see the beam traversing the aqueous fluid he should avoid certain fallacies due to reflections, he should make the slit lamp arm oscillate slowly up and down so as to give movement to this faint beam which thereby will be seen the more easily, and finally, at least when a beginner he should take observation with his own more appreciative perimacular field by directing his gaze deliberately a little above or below the level at which he seeks to see the beam I myself from long practice feel that given use of the same instruments under the same conditions, I can judge of a very slight range within which the relucency of the normal aqueous fluid, though slightly variable may be said to be normal All this might be no more than a scientific curiosity were it not for the fact that slight pathological increase in the relucency of the aqueous fluid occur in various abnormal conditions, an account of which has not, so far as I am aware, yet been forthcoming I have long made this a subject of clinical observation, and I am still doing so, for there are many points in connexion with it which I wish yet to find out, concerning not only the conditions in which this pathological increase of relucency occurs, but particularly also the incipient stages in such diseases at which this sign first manifests itself I touch on this aspect of the abnormal only to emphasize how desirable it is clinically for the observer so to have trained himself that he can appreciate the range within which the relucency of the aqueous fluid may be said to be normal

It should be understood that when speaking of this visibility of the path in the normal aqueous fluid I speak of a homogeneous "flare"—the 'outstanding beam" The brightness of this flare is variably increased in various pathological conditions Writings on pathological conditions show lack of proper distinction between the visibility component due to the flare and that due to discrete particles which are visible as such both factors can contribute to visibility of the path in pathological states but commonly the former exists alone When the arc slit-lamp is used occasional isolated illuminated particles may be seen to cross the beam track even in an eye which may be presumed to be normal, I believe that such particles when very few and when unaccompanied by any increase in the visibility of the normal homogeneous flare component are not necessarily indicative of past or present intraocular trouble With certain reservations, the discrete particles are generally seen better when illuminated by the ribbon-like slit beam than by the pencil-like dot-beam I might here add that as Mr J E Barnard informs me, the visibility, when due to particles of an order of size and distance of separation which is below the lowest limit of admitting of resolution is due to scattering of light but that in the case of particles which are visible as such their visibility is due to diffraction

I will now refer to the second point which I wish to introduce to-day A problem which interested me early in the study of the optical section of the lens was this any observer may notice, early in his experience that there is an inconstant feature of the optical section of the posterior, and sometimes anterior, lens-cortex—namely that a restricted portion of this will often differ from the rest of the lens section by having an almost metallic lustre This may be seen at its best in many a senile cortex but you may also sometimes see it though it is less delicate and elusive, in the cortex of some young people Not only does the extent to which this phenomenon is seen vary in different individuals but its manifestation varies in the same individual according to the optical conditions of adjustment of the slit-lamp apparatus Let Fig 5 represent the optical section in the posterior part of a lens let c be the capsular line and r the subcapsular or reduplication line the posterior cortex being represented by an area in front of r At times and in certain individuals you will find that a variably restricted area which for diagrammatic purposes we may represent by s in the optical section, comes to assume a metallic lustre in colour sometimes faint and golden sometimes rich and copper-bronze I need not go into all the explanations by which early I tried to satisfy myself as to what this meant I first wondered if it could be due to some phenomenon of scattering by structural elements in the cortex of the light which, after being specularly reflected from the posterior capsule was passing on its return journey forward, but this clearly was not the case, because in the first place the phenomenon somewhat modified is seen in the anterior cortex which in most lenses is not bounded posteriorly by any surface of high specularly-reflecting quality as is the posterior cortex by the posterior capsule and moreover, were this the explanation this appearance would be situated within the optical section itself only when the incident axis of illumination corresponded with the normal to the curve of the posterior capsule

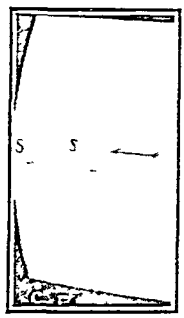

Fig 5.

In one of the first cases in which I noticed this appearance in a young person it took the form of quite a narrow vertically disposed band, and, as another explanation I wondered if its plane might be transposed transversely to the plane of the sectional beam and whether it might be due to a single additional reflecting surface situated just in front of the line r for when this area s chances to be narrow it is by no means easy, for one not knowing its proper explanation to say whether the lustrous area is disposed transversely or anteroposteriorly especially because its appearance is modified by the chosen angle of observation and therefore its stereoscopic appreciation is inevitably difficult when the observer is using a binocular microscope whose objectives are disposed at different respective angles

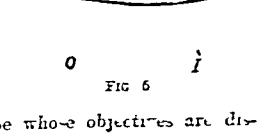

Fig 6

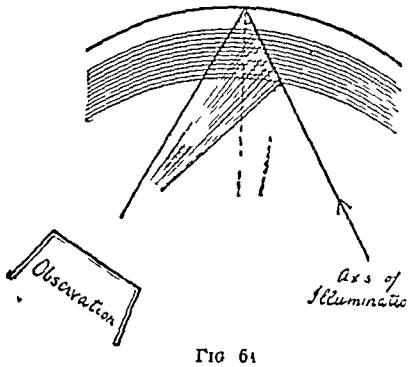
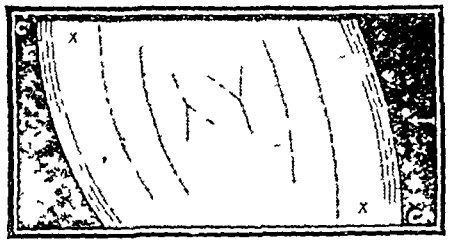
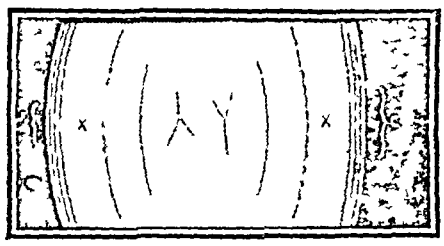
I next found that this appearance reveals itself near to its greatest intensity when the posterior capsule behind r is being viewed along the axis of its specular reflection, in Fig 5 s' represents the small area of the posterior capsule which is being viewed thus—that is it is being viewed by ordinary direct illumination (Fig 6), with the added necessary condition that the chosen axis of observation through the microscope makes with the normal a plane angle equal to that made by the incident axis of direct illumination Furthermore, the metallic cortical lustre disappears

when the relation of these angles differs widely from that necessary for seeing the posterior capsule in its specular reflex. This provided the key to the explanation of this manifestation in the optical section of the cortex. It is impossible now to go into the many aspects of this phenomenon, all of which are accordant with an explanation that it results from a summation of successive multiple specular reflections of a sort which, under the conditions I have named, occur from the stratified or laminated structural elements of which the cortex is built. This conception is represented purely diagrammatically in Fig. 6A. For example, the appearance is seen in general over an area of the beam which, though restricted in its extent, is nevertheless vertically much wider than would correspond with the size of the particular area of the posterior capsule behind it, which for the moment is seen in the axis of its specular reflection, this is because the cortical laminations are not so regular in their curved configuration, and it may be also that if approximately regular they differ slightly in the radius of their curvature from that of the capsule. Again, the manifestation disappears from any given region of the observed lens as this is tilted by making the patient move his gaze up or down a given vertical line, the lustrous area remaining, so to speak, in the "beam-region," but changing its disposition by a movement which is modified by, but does not accompany, the apparent direction of motion of the cortex. I may illustrate this by the three Figs. 7A, 7B, 7C. It is assumed that the slit-lamp arm and the axis of the observation system are in a horizontal plane, and that, without change in the angular disposition of these to the normal in the horizontal plane, Fig. 7A represents the appearance when the eye is looking upwards, 7B when it is looking horizontally, and 7C when it is looking downwards. In general, in a suitable case, more especially in one with a senile cortex, the specular manifestations X, X' might be seen to change their distribution and their position according to the vertical direction of the eye, as shown in these figures, in which X and X' are respectively in the anterior and posterior cortex, C and C' representing the arcs of the anterior and posterior capsule respectively, which, under the conditions of the moment, is seen in the approximate axis of specular reflection. Space does not permit me on this occasion to give simple diagrams explaining this, but its explanation—as that of other features, as well as differences between the manifestation as seen in the anterior and posterior cortex respectively, due partly to the laminations in the one being convex and in the other concave, and partly to a difference in their radius of curvature—and also that of certain changes which may be seen as age advances, may be based on the assumption of a summated specular manifestation occurring along the course of the sectional beam as the result of multiple lamination of structure. I have reason to suppose that from the very even of adolescence changes may occur in the character of the optical section of the cortex of some individuals which explanation can be understood only on the basis of this view.







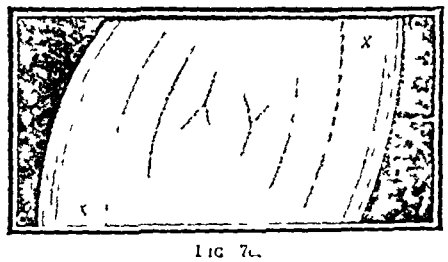


FIG. 6A.

FIG. 7A.

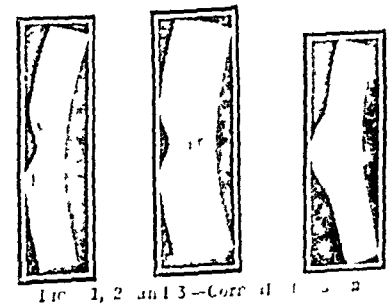
FIG. 7B.

FIG. 7C.

I think that prolonged observations by more than one observer will be required if it is to be ascertained why this manifestation should differ as it does in different individuals. Furthermore, I am not sure that prolonged study of many individuals may not lead to a recognition of presenile cataractous changes which might have some bearing on the prognosis as to the occurrence of senile cataract.

I would like to refer, in conclusion, to my indebtedness for the facilities which have been afforded me when pursuing this work at the Royal London Ophthalmic Hospital and at the Royal Westminster Ophthalmic Hospital.

H. T. HARRISON BUTLER, M.A., M.D. OXON.,
Surgeon, Birmingham and Midland Eye Hospital, Honorary Ophthalmic Surgeon to the Coventry and Leamington General Hospital



THE PATHOLOGICAL ASPECT

MR. BASIL GRAVES has opened our discussion with a lucid account of some appearances of the eye as seen with the Czapski binocular microscope under the illumination of Gullstrand's slit-lamp. I thank you for asking me to continue the discussion from the pathological side.

It is obviously impossible for me in the short time at my disposal to do more than touch the fringe of this vast subject, and I propose to allude only to one or two abnormal conditions in each section of the eye—the cornea, anterior chamber, iris, lens, and vitreous.

CORNEA

The depth and extent of a corneal ulcer can be accurately measured by using a micrometer eye-piece, but from the clinical standpoint it can be estimated by mere inspection of the optical section of the cornea. If stained with fluorescein we can see that the green coloration passes along the lymph spaces and penetrates deeply into the substance of the cornea. This will explain how easy it is for septic material to spread in the tissues of the cornea and why a septic ulcer so often gives rise to exclusion with the formation of hypopyon. Figs. 1 and 2 show the appearance of a corneal ulcer, and Fig. 3 the heaping up of tissue that has followed the healing of an ulcer.

FIG. 1, 2 and 3.—Corneal ulcers. 1 and 2.

Superficial keratitis takes many and varied forms. It is probable that the slit-lamp will help us to make a more exact and scientific classification, certain it is that the appearances suggest the existence of many distinct pathological states hitherto roughly grouped together under the comprehensive terms "superficial keratitis," "dystrophia corneæ," or "bullous keratitis." On the other hand, some of the varieties labelled with definite names, such as "alphabet keratitis," prove not to be pathological entities. The essential point of distinction is its location. The slit-lamp with its accurate localization enables us to decide that the abnormal state is wholly upon or external to Bowman's membrane, that it is located in the corneal stroma, but in its outermost lamellæ, that it is interstitial, or that it is confined wholly to the deeper tissues

of the cornea, perhaps affecting the endothelium alone Fig 4 is an example of a perfectly superficial keratitis a case that caused me considerable anxiety till the slit lamp examination showed that the whole process was external to Bowman's membrane

Herpes ophthalmica may cause a characteristic lesion lying in the superficial layers of the stroma just inside Bowman's membrane Fig 6 shows the appearance of the cornea examined with loupe and the focal illumination of a half-watt lamp The view with the Czapski microscope is seen in Fig 5 The difference is striking and is a good example of the value of the slit lamp Fig 7 portrays a late stage in a severe example of corneal inflammation in connexion with herpes ophthalmica The whole surface of the cornea is covered with plate like calcified deposits

Fig —Keratitis epithelialis

Fig 5 and 6—Herpes of cornea

Keratitis Disciformis—Fig 8 was drawn from a case at any rate simulating this disease There was a history of a trivial accident to the cornea The section (Fig 8a) shows that there is a fibrosed disc situated superficially in the substantia propria and that the whole thickness of the cornea is vascularized Here again the slit-lamp gave useful information, for examination with the loupe led to the erroneous conclusion that the vessels were in the main at any rate superficial

Fig 7—Calcification of cornea after herpes.

Fig 8—Discoid keratitis following injury

Fig 8a—Fig 8 seen in optical section

Central Keratitis—This affection, which is said to be tuberculous in nature, may leave permanent radial folding of Descemet's membrane and occasionally of Bowman's

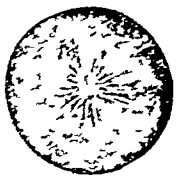


Fig 9—Radial folds of Descemet's membrane

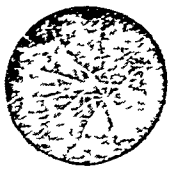

Fig 10—Folding of Bowman's and Descemet's membrane.

Fig 9 shows folds of Descemet's membrane of the radial type, and Fig 10 folds of both membranes

Folding of Descemet's membrane can be seen with the slit lamp in most inflammatory states of the anterior segment of the eye and are almost constant after operation upon the cornea They are invariable present in interstitial keratitis Typical examples are seen in Fig 11 They followed a preliminary iridectomy Two days later no trace of folding could be seen We must make a distinction between true and false folds, the latter being in reality tears in the membrane

Interstitial Keratitis—A description of this disease as seen by the slit-lamp would demand a lecture to itself I must therefore confine my remarks to two points alone In a late case which we might regard as cured leaving the usual rests or shades of a past vascularization visible with the loupe by oblique illumination, we may find that the vessels are not as imagined, functionless and atrophied, but that they still carry an active blood stream—that the disease is in fact by no means at an end Here again the slit-lamp gives information not previously at our disposal It is true that in many of these cases a correct use of loupe and illumination will permit us to see the flowing blood without using the slit lamp, but there are others in which the vessels are so tenuous that the blood stream can be detected only with the Czapski microscope When we examine the corneal prism in this type of case a parenchymatous keratitis that has run its course we note that it is quite difficult to get a clear sharp image of the epithelial surface but that the endothelial is easy to see This is due to the fact that the posterior surface of the cornea is coloured and reflects light better than the corneal surface This appearance is quite characteristic of the disease

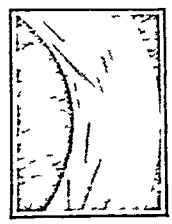

Fig 11—Folds in Descemet's membrane after operation.

Anterior Chamber

The examination of the anterior chamber with the slit-lamp is of the very highest importance with reference to inflammatory states of the anterior segment of the eye Keratic precipitates ("K P") can be detected when so small that they are apt to be overlooked by the older methods and under high magnification much can be learned about their nature and significance We are liable to regard flakes of absorbing cortex upon the surface of the cornea as mutton fat "K P" and to become unduly alarmed Black K P is very common after operation involving the iris and I regard it as perfectly harmless It peppers the anterior surface of the iris and settles down upon the lower two-thirds of the cornea After a perforating wound of an iris and especially of a brown iris the aqueous is full of particles of pigment which may be found for several days The detection of floating particles in the aqueous is of supreme importance We use the pinhole which forms the ribbon of the slit-lamp in a pencil This beam illuminates the cornea and lens but the anterior chamber should remain dark If the aqueous is albuminous the beam becomes visible in the anterior chamber and the brightness of this beam is a measure of the turbidity of the aqueous Fig 12 and 13 show the beam passing across the normal and the turbid aqueous In the aqueous contains formed particles these flash across the beam as scintillating specks Their motion is due to convection currents in the aqueous caused by difference in temperature of the iris and cornea The detection of cellular elements in the

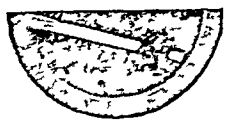

Fig 12.—Normal aqueous.

Fig 13—Albuminous aqueous.

Fig 14—Particles seen in beam across anterior chamber

(Owing to the small size of the reproduction these particles are not well defined.)

aqueous may be the first sign of a sympathizing ophthalmitis and can give timely warning of this formidable condition (Fig 14)

Iris

The great advantage of the slit-lamp in the examination of the iris is that in addition to giving a highly magnified *stereoscopic picture* of the superficial area it enables us to illuminate from behind and see the iris in lens-light If there is any atrophy of the retinal pigmentary layer or holes in this tissue the light shines through and the condition is made evident

Lens

The various forms of cataract can be localized and minutely examined with the slit-lamp and Czapski microscope It is often possible as the result of this localization to decide at what period of life an opacity developed

Each region of the lens is liable to its own type of cataract Immediately under the capsule we find vacuoles and lamellar cleavage The cortex shows cavities full of fluid (the so-called "fluid-clefts") and areas of degenerated fibres (myelin clumps) The central nuclei are liable in old age to sclerosis and to pigmentation The anterior part becomes dark yellow, and, as we pass back, the yellow gives place to a burnt-sienna brown, which in cataracta nigra becomes almost black in the posterior part of the lens The *infantile and the embryonic nuclei* are the seat of congenital cataracts and of lamellar cataracts Many so classed are not really lamellar, but in the familial type affect the whole of the embryonic nucleus Such a cataract seen in the beam of the slit-lamp looks like a lump of crystalline ice placed in the exact centre of the lens In lamellar cataract we very frequently find that there is, in addition to the main central wreath of scintillating *particles*, one or more peripheral rings of condensed lens tissue, showing that the disturbance of nutrition has been periodic

Capsular cataracts of varying types are common, and cannot be dated chronologically, for the capsule has covered each nucleus in turn Many deep-seated axially placed cataracts may originally have had a subcapsular origin As the capsule during the growth of the lens is constantly changing its situation with reference to the nuclei it leaves subcapsular opacities behind it The lens sutures are apt to be the seat of opacities, and this is especially true of the primary embryonic sutures, the anterior and posterior "Y" Coronal cataract, or cataracta coerulea punctata, is generally regarded as a congenital type This cannot be the case, for its situation is in the adult nucleus which has *not* developed at birth I have myself observed this form of punctate cataract appear in a previously clear lens, and I have noted a rapid deterioration of sight Cataracta *coerulea* is neither congenital nor is it stationary It develops during adolescence

The slit-lamp has furnished so much information regarding the anatomy and the pathology of the lens that all textbooks are obsolete in this connexion From the operative standpoint the slit-lamp is indispensable, for it gives an accurate knowledge of the nature of the cataract that we propose to extract or needle, and allows us to detect the earliest signs of inflammation both before and *after operation* I should not now dream of operating upon a cataract till I had made a minute examination with the Czapski microscope, and I have already refused to extract a lens that I should have operated upon had the slit-lamp not forewarned me of a chronic cyclitis I was able to decide that one eye was fit for operation, the *other* undesirable

Vitreous

The appearances of the vitreous are varied and often very beautiful It is hard to realize that a normal perfectly transparent vitreous is actually full of massive shreds of fibrillar consistence and innumerable opacities It is difficult to explain its physiological from the pathological, unless we assume it is maintained by constant application and by experience like appearances can be shown

lamp must be compared with what is detected with the ophthalmoscope with the loupe and condensing lens It is not generally known that the vitreous structure can often be made out with such simple apparatus as a half-watt lamp, a loupe, and a condensing lens

Retina

The examination of the retina with the slit-lamp calls for special arrangements and a high degree of technical skill It is necessary to use an arc lamp instead of the convenient nitra lamp, a contact-glass to abolish the corneal curvature, and either to employ a single tube microscope, *or to hang the slit-lamp* above the Czapski, so that the axis of the *slit-lamp* beam may make a very small angle with the axis of the microscope I cannot regard this *branch of the work as coming within the scope of ordinary* clinical work, but upon occasions it may afford valuable information about an intraocular tumour Those interested in the subject should read Koeppe's book

In conclusion, there is in my mind no doubt of the value of the slit-lamp I consider that one who has made himself master of the technique and has given enough time to the subject has raised himself to a plane of ophthalmology higher than he previously occupied

---

III.—CHARLES B GOULDEN, MB, FRCS,

Ophthalmic Surgeon, London Hospital

THE best result by focal illumination can be obtained only when the illuminating source is *brought to a focus upon* the object to be examined *The advantage of this* is that *we only illuminate what we wish to examine, excluding light which might fall upon surrounding structures* in other words, we have our object brilliantly illuminated and seen in contrast with surrounding structures, which are in the dark The source of light must be uniform, strictly limited, with a high specific intensity, and a sharp image of this source must be obtained

All these conditions are found in the slit-lamp We use the slit-lamp with the source of light and the various focusing apparatus, arranged after what is called "the method of Vogt" The source of light, which is a small tungsten lamp, is placed a little behind the principal focus of the lens contained in the condensing chamber By this means the filament of the lamp is brought to a focus upon the focusing lens The slit, which is placed a small distance in front of the condensing lens, becomes *uniformly* filled with light and acts as the source of illumination The beam of light, therefore, contains in it two systems one, the image of the *filament which is brought to a focus upon* the focusing lens, and the other the light which is contained in the slit and which will be brought to a focus by the focusing lens in whatever position we *choose*

I do not wish to speak this afternoon of the slit-lamp as used merely as a method of focal illumination, but of the behaviour of the cornea and lens as mirrors when the image of the slit is focused upon them or in their neighbourhood The anterior surface of the cornea, and also its posterior surface, act as *convex* mirrors The anterior surface of the lens also acts as a convex mirror, but its posterior surface acts as a concave *mirror*

All mirrors show three methods of reflection (1) Light reflected regularly will produce an image of a luminous source at the point where the rays meet This may be either a real image or a virtual image—*when the rays* appears to come from a point behind the *mirror* Such an image will be seen only *when the eye is placed in the path* of the reflected rays (2) *Light is also* reflected diffusely in the same way as light is reflected from any object that is visible to us it is, in fact, the light reflected by the mirror so that the mirror may be seen by anyone in the neighbourhood (3) There is another method by which rays are reflected which gives rise to what is called *specular* reflection You are all acquainted with the phenomenon made by a blackboard which prevents your seeing what is written upon it This is an example of specular reflection

The Reflecting Surface of the Eye

Reflection will occur at each zone or discontinuity of surfaces where the index refracting suddenly alters These are

1 Anterior surface of the cornea
2 Posterior surface of the cornea
3 Anterior surface of the lens
4 Anterior surface of the adult nucleus
5 Anterior surface of the embryonic nucleus
6 Posterior surface of the embryonic nucleus
7 Posterior surface of the adult nucleus
8 Posterior surface of the lens

Diffuse Reflection

As the beam of light passes through the various media of the eye it illuminates each surface as well as the substance of the medium itself At each place where the beam strikes a surface a band of light is produced, owing to the peculiar ribbon shape of the beam In this way circumscribed portions of surfaces and media are illuminated and so become visible by diffuse reflected light to anyone in the neighbourhood

Regular Reflection

The more polished a surface, and the greater the difference between the refractive indices of the bounding media, the more light it reflects the greater the angle of incidence the greater the amount of light reflected The least amount of light is reflected when the incidence is normal to the surface

The Formation of Images and the Inter or Surface of the Cornea

The cornea is a convex mirror having a radius of curvature of about 8 mm , the principal focus is therefore 4 mm behind it We have three possible relations between the image of the slit and the cornea

1 The surface of the cornea may be at the focus of the beam of light In this condition the image of the slit coincides with the band of light which is formed by diffuse reflection

2. The surface of the cornea may be situated in the post focal part of the beam, the rays therefore when they strike the cornea are divergent The image of the slit is therefore formed behind the cornea between it apex and principal focus

3 The surface of the cornea may be situated in the pre focal part of the beam—that is, the cornea is cut by the ribbon of light before the rays have come to a focus The image of the slit now depends upon the relation of the focus of the beam to the principal focus of the mirror

(*a*) If the rays come to a focus between the apex of the cornea and its posterior focus then the reflected image of the slit will be in front of the cornea

(*b*) If the image of the slit is formed at the principal focus of the mirror, then the image formed by the cornea is at infinity

(*c*) If the image of the slit is formed between the principal focus and centre of curvature of the cornea the image formed by the cornea is behind the centre of curvature

(*d*) If the image of the slit formed by the rays is at the centre of curvature of the mirror, here also will be the image formed by the cornea

(*e*) If the image of the slit is formed behind the centre of curvature of the mirror then the image formed by the cornea is between the centre of curvature of the cornea and its principal focus

We have mentioned before that in the beam which leaves the slit there is also the image of the filament of the lamp which we focus upon the focusing lens The image of the lens with the contained image of the filament will also be formed in the cornea Now the focusing lens is always further from the cornea than is the image of the slit The image of the focusing lens is consequently formed, and always lies, between the apex of the cornea and its posterior principal focus, for example, the condition in which the image of the slit is formed by the focusing lens between the apex of the cornea and the principal focus The catoptric image of the image formed by the lens is therefore in front of the cornea If now we focus a microscope gradually towards the cornea, we shall first note the catoptric image of the slit formed by the cornea, then as we advance the microscope to the cornea the band of light formed by diffuse reflection, and, as we focus still deeper, we shall encounter the image of the focusing lens with the contained image of the filament of the lamp and the band of light in the cornea We shall also encounter in the band the peculiar reflection referred to previously, this is always smaller than the band of light in the cornea Until Vogt pointed out the clinical use of specular reflection it was always considered to be a nuisance and every attempt was made to avoid it Certain things may however, be seen in the area of specular reflection which cannot be seen by any other means these are chiefly minute inequalities of the surface, such as changes in the superficial epithelium due to glaucoma and small irregularities of the epithelium

Reflection from the Posterior Surface of the Cornea

The reflection from the posterior surface of the cornea is not nearly so bright as that from its anterior surface, mainly due to the fact that there is a very small difference between the index of refraction of the cornea and the aqueous The light reflected from the posterior surface of the cornea is yellowish, this is due to the fact that the light before it reaches the observer has to pass through the thickness of the substance of the cornea, where a good many of the rays of shorter wave-length are absorbed So as to observe the light reflected from the posterior surface of the cornea we must have a large angle between the illuminating source and the normal to the cornea, and observations must be made at an equally large angle on the other side of the normal It is chiefly the specular reflection which is of value We are actually able to see in a magnification of no more than twenty-four times the endothelium of Descemet's membrane and certain changes that take place in it

The Anterior Surface of the Lens

The anterior surface of the lens acts as a convex mirror, and we shall have similar phenomena to those seen when the beam of light was focused upon the cornea The anterior capsule of the lens is not perfectly smooth The result is an appearance in specular reflection of a fine shagreen Not only this but there is also present a peculiar lustre due to the difference between the images seen by the observer in either eye with the binocular microscope You will remember that picture for use with the spectroscope one of which is black and the other white when fused together give a lustre very much like that of a surface polished with black lead.

The Posterior Surface of the Lens

From the posterior surface of the lens the appearance of shagreen is also found in specular reflection and Vogt has pointed out that in such diseases as retinitis pigmentosa there is a peculiar iridescence from the posterior surface of the lens before any actual opacity has occurred It is an important clinical fact and by it we are said to be able to distinguish a complicated cataract from a senile cataract This peculiar iridescence may also be obtained from the capsule left after extraction of a senile cataract From the surfaces of the adult and embryonic nuclei no similar phenomena can be observed Apparently this is due to the very slight difference in the index of refraction between the various layers of the lens We are however able to see various bands formed as the beam of light passes through the lens

IV—ON GAYER MORGAN, M.Ch., F.R.C.S.

Assistant Ophthalmic Surgeon Guy's Hospital; Ophthalmic Surgeon Royal Waterloo Opthalmic Hospital

For the purpose of this short paper I have collected a series of cases of cyclitis and I am going to deal with certain points which have been noted from time to time The cases chosen showed the usual features the symptoms being marked loss of vision and the obvious sign in most cases—keratitis punctata and vitreous haze Iritis in association with the cyclitis was a variable factor being in some quite a marked feature and in some apparently absent Of the 15 patients, 11 were women and 4 men The Wassermann reaction was positive in 7 cases, negative in 5 cases and not obtained in 2 cases

The first feature I wish to consider is the keratitis punctata This could be seen with the loupe in 9 cases it was found only with the slit-lamp in 4 cases, and was apparently absent in 2 cases In these latter not only was there no gross keratitis punctata, but no trace even of the dust-like deposit could be seen on the endothelium, and the endothelium itself in the central area of the cornea showed none of the changes usually associated with ocular inflammation I have no note in these cases as to whether the amount of pigment in the keratitis punctata varied with the amount of pigment in the uvea, but some recent cases have made me think that this is a true relationship, and that those eyes with much pigment, brown irides, and tigroid fundi show a darker type of keratitis punctata The aqueous flare, when looked for with the precautions described by Mr Graves, was present in nearly every case, and in most of them definite formed particles could be seen It is a curious fact that these particles are almost invariably seen moving upwards, and that, although they must all move downwards in the convection currents, it is the rarest thing to see this happen in the aqueous beam The flare is best seen with the smallest cylindrical beam of light, whereas the particles are most obvious when the slit is fully open and a large beam is used The presence of deposit on the anterior lens capsule seems to have no relationship with that on the endothelium covering Descemet's membrane As a rule it seems to avoid the anterior lens capsule, and this may be due to the influence of the convection currents in some way or to changes in the endothelium which predispose to deposition there There are exceptional cases where it is more thickly scattered on the lens and iris than on the endothelium, and in these cases it is noticeable that the iritis is a *more dominant factor*

In most of the cases subcapsular vacuoles could be seen They are often more easily spotted with the electric ophthalmoscope than with the slit-lamp, as the field of observation is so much larger, and they are easily missed with the small beam of the slit-lamp When their position has been noted with the former method they can then be found and studied with the corneal microscope They are like very bright spheres of varying size on the surface of the lens, and throw a shadow into the lens when illuminated *from in front* They *may easily be missed* with the ophthalmoscope when the vitreous is very cloudy and the brightness of the red reflex dimmed in consequence

In five cases definite iridescence of the posterior capsule was visible in the reflecting zone This indicates that the usual mirror-like reflex from this surface has been changed by some roughening or thickening in the capsular area, causing some interference with the normal action of the beam of light The iridescence, except in one case, was present without there being anything in the nature of a posterior cortical opacity secondary to the inflammatory condition which could be seen with the ophthalmoscope or the slit-lamp In the one exception there was a typical secondary cataract in the neighbourhood of the posterior lens sutures with very brilliant iridescence This iridescence seems to last a very considerable time, because in two cases with positive Wassermann reactions, in which the condition has improved under treatment and the vision is now 6/6, it can still be very easily seen In both these cases, however, there is still a very marked though extremely fine vitreous haze visible with the ophthalmoscope The changes producing this iridescence must be extremely fine to cause such a minimal interference with the visual acuity

Behind the lens is the retrolental space, which normally is optically empty Usually in cases of cyclitis this space remains optically empty, although the vitreous may be densely packed with deposits This is not constant, however, and occasionally one sees formed particles which seem to move in this space

Bounding the retrolental space behind is the anterior curtain of the vitreous It lies in folds, which in some places hang vertically and in others look more like a meshwork of vertical and horizontal strands Normally it floats up and down with movements of the head, and if it is attached somewhere in the ciliary region it certainly has a considerable amount of slack If the anterior layers of this curtain represent the hyaloid, then this latter is not the tightly stretched membrane one has usually been led to consider it With the patient in the upright position the curtain is seen, on movement of the eye, to float downwards until it is drawn taut by its attachment above It is probable that there is an attachment all round in the ciliary region, and that if the eye is examined with the patient in the reverse position this attachment would be demonstrated It would be interesting to examine the eye with the patient in the prone position to investigate the retrolental space, but this is not yet possible with the present instrument In one case this anterior curtain could be seen to be definitely attached to the posterior surface of the lens, so forming a loculation, as it were, of the retrolental space The rest of the curtain moved freely, pivoting on this attached point I presume that this vitreous synechia may be considered as analogous with the iris synechiæ and be possibly of inflammatory origin The meshwork of the vitreous in these cases of cyclitis contained a very much larger proportion of formed particles, mostly pigmented granules, than normal I had a feeling that in those specific cases the particles were much finer and more uniform in size than in those with a different etiology and in which some septic focus was responsible for the condition, but Mr Graves tells me that the largest opacities he ever saw were in a case of congenital syphilis It is difficult to say how long it takes for the vitreous to become quite clear of these pathological particles In the two cases I have mentioned before, where vision is now 6/6 and has been so for some months, and where the actual condition is presumably cured after a full course of N A B + mercury, the vitreous is still densely packed and the haze is quite visible with the ophthalmoscope

GENERAL DISCUSSION

Mr Humphrey Neame (London), for his contribution to this discussion of slit-lamp microscopy, took the description of a case in which detailed examination had been much facilitated by the use of this special apparatus The particular interest of the case was that the termination was not of a particularly common type The case was one of posterior stellate or rosette opacity of the lens following trauma, in which the opacity disappeared completely in the course of a few weeks

Hudson, in a "Clinical study of posterior traumatic cataract" (*Royal London Ophthalmic Hospital Reports*, xviii, 112), had described forty-three cases of different types of such opacity, in the course of the development of which from a short time after the receipt of the injury, he traced the following appearances in the more typical cases in the order of their occurrence (1) Feathery streaks in connexion with the lines of the lens star, (2) vacuoles in the midribs of the feather-like opacities, (3) lacework replacing the feather-like structure, (4) vacuole formation, particularly towards the equatorial region, often in palisade formation parallel with the lens fibres, (5) breaking up of the opacity into discrete vacuoles, which gradually become smaller until only a few granules of opacity remained

Hudson believed the opacity to be due to swelling of the lens fibres of the posterior layers, and produced a number of arguments in support of this, also that it had no connexion with aqueous action, for it occurred equally with penetrating and with non-penetrating injuries

In Hudson's series only two cases out of the forty-three had resulted in complete disappearance of the opacity, in one of these the lens was completely clear three months after a penetrating wound of the cornea, without penetration of the lens and without retention of a foreign body in the eye (*x*-ray evidence and magnet negative), in the other there had been a small scleral wound with the presence of a foreign body in the vitreous, but without penetration of the lens The foreign body was metallic and was removed by magnet eleven days after injury The opacity had disappeared eleven days after operation In the former the opacity was composed of irregular vacuoles, in the latter it was a small posterior-disc opacity In fifteen cases general opacity of the lens subsequently developed, and in the others variable degrees and types of posterior opacity persisted

Mr H Whiting, in his description of concussion changes in the crystalline lens (*Trans Ophth Soc*, xxxix, 1919, 169), had included in his posterior cortical [illegible]

seven of stellate variety These were the result of war injuries, and were only under observation for short periods, so that from the point of view of absorption of opacity, they are of less value Of the seven posterior stellate cataracts one was in part absorbed in thirty eight days from date of first observation (within two or three days of injury), and one was lessened in ten days Both of these were concussion injuries only The other during short observation, remained stationary or increased in density

Vogt (*Atlas of Slit lamp Microscopy* Berlin 1921 p 80 and Fig 202b) had described and illustrated a typical posterior rosette-shaped subcapsular cataract in a patient in whom the cornea, iris, lens and vitreous had been penetrated by a needle It was present within thirty six hours of the time of injury, and then measured 4 5 mm in diameter In ten days it had diminished to 2 mm diameter, in twenty days to 1 mm diameter, and in six weeks was represented merely by a few dots of opacity at which date V =6/6 Vogt described the opacity as composed of minute droplets under the posterior capsule and also between the posterior lens fibres as in the opaque area the suture and lens fibre pattern were strongly delineated

Mr Neame's case was a patient at the Royal London Ophthalmic Hospital, under the care of Mr Juler, to whom he was indebted for permission to report the condition John H , aged about 40, was injured in the left eye by a fragment of metal on April 20th, 1924 The cornea and iris were perforated, but no fragment of metal was retained in the eye Seven days after the date of injury Mr Neame made the drawing of the cataract—a typical feather like posterior stellate opacity—under examination by slit-lamp microscope The opacity had been reported two days earlier by the house surgeon—that is, five days after injury It was of an almost completely symmetrical eight-pointed star shape, very similar to the one shown by Vogt The opacity was not measured, but occupied a decidedly longer transverse diameter than that of the widely dilated pupil, for the apices of the arms were barely visible by examination with the microscope in an oblique direction behind the iris The drawing shown therefore represented the composite appearance of the opacity as examined obliquely in every direction, and not as seen directly antero-posteriorly through the pupil Under higher magnification (obj V 2 and I P 2= ×24 diameters) of the edge near one point the opacity was seen to be composed of elongated ovoid portions resembling those described by Hudson—like the juice sacs in fruit such as an orange It seemed to Mr Neame probable that the appearance was due to irregular swelling of the lens fibres, as suggested by Hudson, and not to vacuole formation between them

Seventy-one days after the above observation was made there was no trace whatever of lens opacity, only a somewhat increased brilliance of the posterior reflecting zone of the lens, beyond which the vitreous was visible Left vision +3 0 sph =6/12 partly

Mr Basil Graves, in reply to the criticism that the path of the beam could not be seen in the normal aqueous fluid, remarked that the path of the beam in the normal aqueous fluid was clearly visible if the precautions advocated were taken With the arc-lamp it was evident to a novice When the more ordinary nitra-lamp was used it was essential that the resistance should be regulated so that the filament was burnt at its brightest intensity and the dark room should have no leakages of light It was not correct to say that a long period was required for the observer's dark-adaptation the speaker had found that a few seconds were always enough He thought that ability to recognize the visibility of the beam in the normal aqueous fluid was important in the sense that notes on a case affirming an aqueous fluid to be normal were of greater clinical value if made by an observer who was able to see the beam in the normal aqueous fluid than if made by one who was not so trained It was much the same, for example, as the relative value of notes which affirmed that a fundus-macula was normal when the observer who made them knew that he had really seen and recognized that macula as compared, on the other hand, with the value of a similar statement made by an observer who, having vaguely seen the region where he supposed that macula to be said that the unseen macula was normal because he saw there nothing obviously pathological In the earlier notes of Mr Graves, taken two to three years ago, which were the subject of a research report he was now making, he regarded the frequent statement in them as to the aqueous fluid being normal of little value save to indicate that it was not grossly abnormal, because he had not then learnt a sufficiently delicate method for his observation On the other hand, he knew that in more recent time his notes on cases stated that the aqueous fluid was normal, he could depend upon that statement, because he would not have said so without having made a point of arranging the apparatus with sufficient accuracy to have seen the beam in that normal aqueous fluid

As regards the question of the vitreous a review of notes made on many cases over a long period was showing him that it was very difficult to draw conclusions about its pathological changes which enabled a classification of clinical conditions to be made fitting in with preconceived notions of clinical types From a purely practical point of view the clinical usefulness of the slit lamp examination of the vitreous in no case came up to that of the simple but valuable method of inspection for pathological vitreous 'dust' by means of the direct electric ophthalmoscope when this instrument was properly used

Mr Happer Butler in reply said he had no hitherto succeeded in seeing the flare in the normal aqueous (This discrepancy was cleared up in the afternoon at the demonstration of the slit lamp When the lamp were used at the normal voltage (8 volt) the flare was not visible even to Mr Graves but when the current was boosted up and the lamp overrun the flare was distinctly seen) It would therefore appear that the visibility was a function of the illumination, and this might be regarded as a test of normality If the flare was easily seen at a voltage of eight the aqueous was probably abnormal The slit-lamp distinctly showed a hyaloid membrane He had obtained a mirror effect from the hyaloid membrane, and on it he had been able to make out a marbling of the surface He did not wish to dogmatize but he thought that the appearances showed that there was a real retrolental space between the lens and the hyaloid, which were optically inactive The vitreous fibrils were he thought attached to the hyaloid membrane and normally did not reach the lens Under pathological conditions the fibrils might be attached to the lens

He agreed with Mr Graves that it was very difficult to interpret the appearances seen in the vitreous, and that such must be checked by careful examination with the ophthalmoscope He regarded fine particles as abnormal in fact, the coarser the vitreous architecture the more it approached the normal

SYMPATHETIC OPHTHALMIA AND ALLIED CONDITIONS

BY

JAMES ALEXANDER WILSON O B E , M D ,

Cambuslang Glasgow

The etiology of sympathetic ophthalmia remains an interesting problem The inquisitive mind finds in the evolution of medical knowledge an ever-changing outlook on this and other problems, the collecting of evidence the expression of opinion, and the clash of criticism are all necessary if we are to make satisfactory progress towards our ultimate goal —the prevention of disease and the maintenance of health

In an article on sympathetic ophthalmia' published some years ago I asked the question How is disease of a particular type transferred from one eyeball to the other' In the conclusion it was suggested that

> In sympathetic ophthalmia—as in tetanus—toxin goes up the nerve and reach nerve cell causing a central disturbance with efferent influences—as in herpes—which manifest themselves first as capillary changes and then as uveitis

This problem may now merit further brief consideration Speaking in a general way, when a soluble toxin is carried in the blood stream, the distribution and manifestations are likely to be 'symmetrical' when there is a microbe virus the distribution and manifestations are likely to be 'asymmetrical"

Disease of the anterior part of the eyeball is usually due to some noxa, circulating in the blood stream, that acts directly on the tissues It may be the virus of specific disease, infective material from any part of the body, metabolic or chemical toxins, but it is a noxa that is diffused generally Certain factors may operate to determine a secondary infection or precipitation and its locality such as trauma—surgical or accidental—local secretion, affinity, local overwork, and possibly the influence of the sympathetic nervous system [2] In sympathetic ophthalmia the disease in the first or injured eye is probably in most cases autogenous, with trauma as its determining factor On the other hand, *ordinary herpes* is a peripheral manifestation of a central nervous disturbance

Messrs Orr and Rows, in their paper[3] dealing with the infection of the nervous system via the lymphatics of the peripheral nerves, showed that where there is an infective focus there is usually an infected lymph stream ascending from it to the central nervous system—a current that lies in the perineural sheaths In a recent paper by Marinesco[4] there is a record of experimental research on the virus of herpes febrilis This virus was inoculated into the corneoscleral margin of a rabbit's eye, it produced keratoconjunctivitis and, later, serious general symptoms After death it was found that the virus had left a track of its passage to the brain There was lymphocytic infiltration in the choroid, ciliary nerves, ciliary ganglion, Gasserian ganglion, and on into the brain The retina, sclerotic, optic nerve, the motor root of the ciliary ganglion, and the common oculo-motor nerves were all practically left intact This is the path of an invisible or filter-passing virus Sympathetic ophthalmia is by some writers also thought to be due to a filter-passing virus but one that makes its way into the blood stream, survives the hostile defensive agencies there, and then, owing to some peculiar affinity, settles in the uninjured eye

In tetanus and diphtheria the virus enters the nerve terminals at the infecting focus in the skin, tissues, or mucous membrane, and ascends in the perineural lymph spaces, so reaching the corresponding basal nucleus or root ganglion In a case of localized tetanus due to the presence of a piece of metal near the brachial plexus it was the shoulder muscles of the same side that manifested tonic spasms In another case a wounded foot was associated with tonic spasms of the corresponding thigh muscles and later with those of the other thigh In diphtheria the palate frequently becomes paralysed In these cases the conclusion is that the manifestations are limited by or "correspond to the nerve supply" Here the invading infective material is not diffused generally or mainly, but is confined it is compartmental or segmental Perhaps there are here the elements of a pathological arc—that is, the receptor, the nerve cell, and the effector segment

The fifth nerve is the sensory or afferent nerve for the eyeballs eyelids, nose, sinuses, gums, teeth, tonsils, skin of forehead, and face The three divisions converge to and enter the Gasserian ganglion This ganglion receiving many ascending streams may thereby have its functions influenced by various noxae and possibly in various ways An interesting and suggestive syndrome is seen in a case presenting trigeminal neuralgia herpes ophthalmicus, and paralysis of the sixth nerve, and in another presenting the same manifestations with the addition of uveitis and anaesthesia of the skin or cornea The neuralgia and the anaesthesia indicate involvement of the Gasserian ganglion, but the paralysis of the sixth nerve indicates that the central lesion has extended to the sixth nucleus Irritation of the fifth nerve may produce a variety of manifestations, that of the sixth nerve is probably limited Occasionally in these cases we also get vesicles on the cornea, and the pain that they cause reminds us that the locality selected is one that has a rich supply of afferent nerves The vesicles on the forehead and cornea and the uveitis are all due to the same primary noxa How are these peripheral manifestations produced? Are we to believe that they are due to a noxa manifesting merely contemporaneous chemical affinity for central and for various peripheral structures, that the central and peripheral lesions are isolated and independent, or are we to believe that efferent or antidromic impulses pass along afferent nerves, impulses capable of producing, Dr Ivy McKenzie maintains—dilatation of capillaries and inflammation? These peripheral manifestations are one-sided, and are limited in area by nerve distribution Further, they are associated with neuralgia, anaesthesia and paralysis, conditions that are dependent on the central lesion

I recently saw two patients with the sequelæ of encephalitis lethargica These patients were under the care of Dr John Rowan, but I have his permission to refer to them Both had paralysis of nearly all the eye muscles on one side with ptosis and dilatation of the pupil One had small bullae on the cornea, and the other keratitis with ulceration of the cornea and later inflammation of the eyeball Here again there is a central lesion paralysis of muscles, and peripheral conditions resembling herpes

Ordinary bullous keratitis may be associated with anæsthesia of the cornea and conjunctiva, in association that suggests a central or nerve origin, probably a neurotoxic condition In herpes ophthalmicus we occasionally get symptoms of sympathetic irritation in the other eye still sympathetic ophthalmia remains a somewhat unique disease, associated with a unique arrangement of the optic nerves The whole neuro-optical apparatus possesses much structural and functional unity

Experiment[5] has demonstrated that when aseptic particles of a choroid, taken from a human case of sympathetic ophthalmia, were implanted into the eye of a monkey, paths of infection were afterwards found leading along the sheath of the optic nerve, "or first along the anterior ciliary vessels out of the eyeball, then along the external eye muscles, and again backwards to the vaginal tissues," or to the optic nerve high up All the affected animals showed changes in the coverings of the optic nerves, and three out of four developed meningitis In this way, even if the optic nerve had been cut (Fuchs), the noxa could still pass up the optic nerve and reach both sides of the brain

If there is an efferent influence, then, in herpes ophthalmicus it travels by the frontal and nasal branches of the ophthalmic division, and in sympathetic ophthalmia perhaps by the nasal branch to the ciliary ganglion or perhaps by some other channel These various allied conditions suggest a mechanism that is largely limited by nerve distribution The direct action of a diffused noxa calls for general treatment, and when a central or neurotoxic element is present this also calls for treatment, sometimes even more so than the local eye condition We have still occasionally to remind ourselves that the eye is an item in a commonwealth and not an isolated entity calling only for individual consideration

MEDICAL, SURGICAL, OBSTETRICAL.

A COMPLICATED CASE OF FRACTURE AT THE BASE OF THE SKULL

The following case, which presents some unusual features, was treated by me recently at the Beckett Hospital and Dispensary, Barnsley, Yorkshire

A well developed man, aged about 30 was thrown from his bicycle during a collision On admission he was bleeding from the right ear, there were no marks of external violence he was very drowsy, but could easily be awakened and to answer questions A diagnosis of fractured base and concussion was made On the following day he was completely unconscious there was slight inequality of the pupils with a right hemiplegia and on careful examination a faint bruise could be seen over the right mastoid process The temperature was 100° F

Operation.—On the right side of the skull a flap corresponding roughly to the outline of the squamous portion of the temporal bone was turned down A fracture was discovered running across the mastoid process and appearing anteriorly through the middle cranial fossa A trephine opening was made just behind the external auditory meatus and enlarged with forceps A dura mater was dark blue in colour, but, on throwing the

was without pulsation A cruciform incision was made in the dura mater and several large blood clots with a quantity of soft normal brain matter escaped The scalp was then sutured the wound being closed without drainage The patient had completely regained consciousness at the end of twenty four hours after the operation

I have to acknowledge the skilled assistance of Dr I Ormond during the operation

OVARIAN CYST COMPLICATING A SIX AND A HALF MONTHS' PREGNANCY

THE case here recorded is of interest partly on account of the longer duration of pregnancy than usual, and partly because the strangulation of the cyst pedicle gave rise to practically no symptoms, there being no pain and only a slight rise of temperature to give warning of the event

A woman aged 18 was admitted to the Government Hospital Apia Samoa on June 26th 1924 She was six months pregnant and had noticed a tumour on the right side of the abdomen in addition to the uterus The day before admission she had acute abdominal pain and thought she was about to miscarry She had noticed the tumour for over two months and also that it enlarged more rapidly than the uterus She had no pain until just before admission and the bladder had given no trouble though the bowels were somewhat constipated She had one child (18 months old) the delivery having been normal

The pregnant uterus occupied the lower half of the abdomen there being a decided list to the left with a prominence extending upward towards the splenic area A tense fluctuating swelling occupied the right side of the abdomen arising apparently from below and behind the right upper margin of the uterus and extending up to and bulging the right lower ribs This tumour was quite distinct from the uterus and was dull on percussion with a marked fluid thrill Vaginal examination revealed a soft patulous os but no sign of commencing labour Nothing was to be felt in the right fornix which was higher than the left the gravid uterus being palpable through the latter By June 28th all pain had ceased but began again on July 2nd and early on July 3rd a live 6½ months foetus was spontaneously delivered it survived for about half an hour The puerperium was normal until July 5th when the temperature rose to 100·4° F it fell below normal on July 6th

On July 7th abdominal section was performed and a large dark brown cyst was found extending right up to the liver which was displaced upwards and backwards The cyst was adherent in places to the liver omentum and parietal peritoneum the latter being inflamed all over and covered with serum and recent fibrin tags *The pedicle was strangulated being twisted two and a half times* on itself and arose from the position of the right ovary The cyst contained port wine coloured fluid The temperature rose after the operation reaching 103·4° F on July 10th it then fell to normal and remained so There was a decided flow of bright-coloured lochia for three days after the operation

R M O Government Hospital Apia Samoa

MULTIPLE ABNORMALITIES IN THE INGUINAL CANAL AND TUNICA VAGINALIS

SEVERAL years ago a man on active service in France complained of a "strain in the right groin" No definite diagnosis was made by the regimental medical officer Since then, on several occasions, he has experienced a sudden drawing up of the testicle accompanied by pain After a recent attack of this kind, unattended by nausea or vomiting the right testicle and cord were found to be swollen, tender, and drawn up to the external ring In a hot bath, after gentle downward stroking the testicle and cord regained their normal position, but further examination revealed the presence of a thickened cord and bubonocele

At the ensuing operation the following abnormalities were found The upper end of the tunica vaginalis lay on the anterior surface of the external oblique muscle and over the external ring The cord was completely twisted five times on itself After it had been untwisted a large pampiniform plexus of veins was disclosed which hung like a septum into the tunica vaginalis When this plexus had been removed, together with the surplus tunica vaginalis, a hernial sac was opened at the upper end of the inguinal canal and was found to contain a mobile caecum, with the appendix adherent to the wall of the sac These various conditions were dealt with in the classical manner

Reports of Societies.

COCAINE ADDICTION

At a meeting of the Society for the Study of Inebriety on October 14th, Sir WILLIAM WILLCOX presiding, a discussion on cocaine addiction was opened by Professor W I DIXON, M D, I P S, Reader in Pharmacology in the University of Cambridge

Professor DIXON said that coca leaves had been used from time immemorial by the Indians in the western South America as a stimulant and narcotic and the habit survived to the present day especially in Peru It was asserted that natives who chewed the coca leaf were able to perform long and rapid journeys with less fatigue and without feeling the pangs of hunger On two occasions in the past the speaker had had injected into himself intramuscularly by way of experiment, about 1½ grain of cocaine The effects gave no pleasure at the time and left none as a memory but each injection produced a frontal headache some little excitement increased reflexes dilated pupils and pronounced insomnia His experience in this respect did not differ greatly from that of many others It might well be that cocaine did not represent the whole action of fresh coca leaves It was probable that coca-chewing allayed the pangs of hunger, which were in some way associated with the alimentary canal by depressing afferent nerve-endings

The action of cocaine upon the nervous system corresponded with the stimulation of the whole cerebral cortex After its injection into animals the cortex was more readily excited by electrical current whilst when injected into normal animals convulsions were produced which could, however be prevented by first severing the crura Moreover there was a relationship between the amount necessary to produce convulsions and the degree of development of the cerebral hemispheres Thus the dose of cocaine, per kilo of body weight required to produce convulsions in the rabbit was 0·18 in the bird 0·06 in the dog 0·03 and in the ape 0·018 grain It was not necessary to offer detailed evidence to prove that the symptoms in man were due to true stimulation Other drugs were known to exert a somewhat similar action but they were happily, now no longer used to produce artificial exultation Loquacity and exultation were sometimes seen after the injection of atropine but the latter would never become a drug of addiction because of its extremely unpleasant actions otherwise The same was true of caffeine the stimulation from which was mild and prolonged

With regard to cocaine poisoning a quarter of a grain produced very little effect on an ordinary person whilst 1½ grains was generally though not always well tolerated The total dose varied from 8 to 23 grains and there was probably not a case on record where cocaine had been used as a murder drug However cocaine like other drugs which especially excited the central nervous system was uncertain in its central action and varied greatly in different individuals, but when death resulted it was believed always brought about by shock caused by sudden paralysis of the central nervous system Mild stimulation of the latter whether by direct or reflex stimulation was followed by all the symptoms of cerebral hyperactivity but if the stimulus exceeded a certain degree the exactly opposite effects were produced He did not think that had been properly appreciated as the cause of collapse and death which sometimes followed the accidental but sudden absorption of cocaine in a susceptible person In every case of death in man from the use of cocaine or other local anaesthetic the symptoms were strikingly similar to those produced in animals The history of mishaps under local anaesthetics always showed that the poisonous action followed almost immediately after injection If one-half a grain of cocaine was injected in one hind limb of a rabbit death occurred in a few minutes but if a tourniquet was placed round the leg after injection and kept there for half an hour toxic symptoms were either very slight or did not occur at all Adrenaline was used in solutions for the

purpose of delaying absorption, and he thought the principle a good one, although it had to be remembered that if absorption occurred the adrenaline considerably increased the toxicity of the cocaine. Much had been written about idiosyncrasy, and it was undoubtedly a fact to remember that cocaine was far more dangerous in concentrated than in dilute solutions. When concentrated there was apt to be absorption into the circulation, whilst if dilute the conditions favoured adsorption to the tissue colloids which rendered the alkaloid innocuous. It was well recognized that man became tolerant to cocaine. With a little practice the dose might be increased as much as 20 grains. The explanation might be, as in the case of morphine, that it was due to increased destruction of the alkaloid, but that suggestion had never been proved. The ordinary laboratory animals did not become less sensitive to regular periodical doses of cocaine, but more so. So far as the question of tolerance was concerned, man therefore occupied a peculiar position in connexion with cocaine.

Turning to the question of addiction to cocaine, Professor Dixon reviewed the position in connexion with the drug prior to the war. It was sometimes said that the addiction epidemic in America, which was such an outstanding social problem there, started after the war or after the prohibition law, but that was not so, for the habit had been steadily growing for a number of years, though post-war conditions probably augmented the numbers. The Congressional Commission in America had stated, in 1919, that 2 per cent. of the whole American people, or 4 per cent. of the adults, indulged in narcotics. Cocaine-taking had spread over the world, but the habit was less prevalent in Europe than in the East or America. In Germany cocaine sniffing was entirely a post-war habit, and confined to the large cities, especially Berlin. In France the habit had been common during the latter years of the war, and had spread from there to Italy, Spain, and England. There was, however, reason to believe that drug addiction was diminishing in France. He had had opportunities of obtaining the powder sold by the habitues of the cafes and music halls in Paris, and each packet contained approximately half a grain of cocaine. It had been too frequently assumed that anyone using the powders was an addict. When cocaine addiction occurred as a single condition it was almost invariably the result of imitation and opportunity, it could be safely said that since the war addiction to cocaine had not followed the physician's prescription. The users of cocaine being a menace to others as well as to themselves, the problem became that of a State menace, and cases should be treated as typhoid and diphtheria cases were, not by making the patient responsible, as the "narcotic police" of New York would have them, but by isolation and effectual removal of the source of infection. The cocaine habit, when once formed, was the worst of all drug habits in that it more rapidly led to the mental, moral, and physical degeneration of the patient than the depressing drugs of addiction. Unlike morphine, cocaine induced insomnia, loss of appetite, dyspepsia, diarrhœa, and, not infrequently, delusions and deafness. In the one hallucination quite diagnostic of cocaine the patient complained of feeling some foreign body under the skin—sometimes like grains of sand, sometimes like worms moving. So far as he was aware that curious symptom was found in no other condition, but was pathognomonic of cocaine poisoning.

Although cocaine so rapidly led to degeneration in uncomplicated cases nevertheless the prognosis was better than in the morphinist. The degree of addiction might best be gauged by the withdrawal symptoms. They were certainly the most severe with heroin, less with morphine, and least of all with cocaine. Even when doses of 30 grains were taken daily cocaine could be dropped at once without serious injury to the patient, whilst similar sudden withdrawal in the case of heroin would certainly jeopardize a man's life. The normal person derived no pleasure from injections of cocaine, though that did not mean that with practice the satisfaction would not come. Who, then, were the people likely to be affected and to derive pleasure from such a practice? In 1906 Sir Clifford Allbutt and he had defined such people as neurotics. Quickness and sensibility, acute perception, and alert muscular reaction were not morbid characteristics, but qualities of high breeding. Such qualities became morbid when developed in relative excess in the lower ranges of sensibility. The higher qualities remaining at their former mean, the controlling centres no longer held the lower centres in check. The ordinary troubles of life became exaggerated out of all importance, but when they took drugs of addiction such people became in a sense more normal. Thus addiction to drugs was very likely to occur in favourable conditions in that type of person, though unlikely to occur in the normal type. Therefore the drug habit, treated broadly, was not a disease but rather a symptom of a pre-existing mental condition. Where it was a disease—in accidental correlation to a normal person—it ought to be readily curable, especially in the early cases, but that was not the case though it was recognized that those who contracted the habit as a result of disease—the relatively normal people—were by far the easier to cure. Americans were now discussing whether drug addiction was a medical issue or a police problem, and the special police commissioner in charge of the narcotic division of the New York police, writing in the *Journal of the American Medical Association* this year, concluded that because addiction had its origin in or was coupled with crime or criminal environment in 98 per cent. of the police cases, therefore the problem was in the category of criminology and came within the province of the police. That savoured of the mediæval method of dealing with lunatics. Drug addicts, in fact, made poor criminals, for judgement, self-control, and will power were lacking. The speaker added that each case of addiction presented a problem by itself, requiring the determination of the underlying cause. Few addicts came willingly for treatment so long as supplies of the drug were available, but fortunately supplies of cocaine were obtained only with difficulty here. He thought the following propositions would meet with few objections: (1) that the prosecution of cocaine traffickers should be carried out by every means at the disposal of society, (2) that some form of international control to prevent illicit importation of cocaine and coca leaves should be established, and here it was of happy augury that the League of Nations had instituted a committee of inquiry, (3) that it was desirable that cocaine should be controlled at the seat of production, (4) that information as to the gravity and danger of narcotics should be spread, not only among medical men and students, but especially among members of the teaching profession.

Discussion

Dr. H. H. Dale expressed his appreciation of the paper, and said that he had been particularly interested in Professor Dixon's description of his own experience of the effects of cocaine. If he had understood him aright, he had experienced nothing which could be called pleasurable, and he had suggested that possibly there was something in the coca leaf which caused the pleasurable sensation said to have been obtained in the instances cited from South America, and that cocaine was not equivalent to the coca leaf in respect to the euphoria the latter was reputed to produce. The speaker did not quite follow him there. He had Professor Dixon considered the possibility that the circumstances of the experiment modified the expected result? From the investigations which had been made on drug addiction it appeared that cocaine addiction differed from others, particularly from morphine addiction, in being totally the result of a social habit. He was told that the secret cocaine-taker was so rare as to be almost non-existent. In other words the vast majority of cocaine-takers acquired the habit in night clubs and other convivial resorts, using it to stimulate their flagging sensations so that they could renew the hectic pleasures which were beginning to pall. But when Professor Dixon sat down in the laboratory surroundings of a scientific laboratory, with no companions to promote his hilarity, the speaker did not think he should expect cocaine to produce the ultra-rich[illegible] tions which people experienced who took it in [illegible] environment. He found it produced in omnia, but,

ill, insomnia was one of the things which the night club habitue went to the night club to obtain, such a person wanted to whip up his brain so as to last out for a longer period. In this respect he imagined that cocaine addicts could be rather sharply differentiated from morphine addicts, the latter took their drug for the relief of pain or some other distress, and not that they might take part in night club enjoyments." He believed that cocaine addiction was practically limited to large cities, it had always been a city vice.

Dr. A. J. Copeland gave an account of some work which he had been doing in Professor Dixon's laboratory on the action of cocaine substitutes on the central nervous system of animals.[1] He had compared particularly butyn, tutocain, novocaine, and psicaine—the latest introduction—in their production of convulsions in laboratory animals when given in small doses. The convulsions to which they gave rise were identical in character, though not in degree, with those caused by cocaine itself. Butyn in these experiments appeared to have twice the convulsive action of cocaine, tutocain approximately half, novocain about one sixth, and psicaine rather less than cocaine. He submitted that these effects gave a valid criterion by which one might judge of the effects of these substitutes in man. Butyn never only was capable of giving rise to severe epileptiform convulsions in man. He had had a personal experience with tutocain, though he believed that Dr. Dale considered it merely a subjective observation. He was using a concentrated solution and observing the effect on the nasal mucous membrane when suddenly he received a mental shock, became excited and restless, and thought he was going to have a convulsion. The effect was very definite, it passed off after a few minutes, and was succeeded by a pleasant exhilaration. He suggested that the properties of these cocaine substitutes might render them liable to be used for their stimulating action, and if that use was continued they might become drugs of addiction. He believed it was a fact that heroin was on the market for ten years before any case of heroin addiction was recorded, therefore the statement that butyn was not a drug of addiction must be taken with some reserve.

Dr. Harry Campbell read a letter he had received from Dr. Francis Hare, medical superintendent of Norwood Sanatorium, who stated that in all his experience he had come across only three instances of the cocaine habit, and those not in recent years. It seemed to Dr. Hare that the habit was very infrequent, though the opposite impression was to be gathered from the newspapers. Many people, Dr. Hare thought, took cocaine for a time, and gave it up after a visit to their *own doctor*. At any rate he had seen only three pure cocaine cases, though he recalled many cases in the old days at the sanatorium—especially cases of doctors—in which cocaine had been used as an auxiliary to morphine. Dr. Campbell took up the remark of Professor Dixon that the individuals *most* liable to drug addiction were those of a peculiarly nervous temperament. But on what did the nervous temperament in general depend? In the speaker's view it depended essentially on the condition of the blood, and not primarily upon the nervous system. The blood normally *contained* stimulants, and to some extent depressants. When the stimulants were in excess the individual had the joy of life, and when the depressants were in excess he was miserable. It had occurred to him that the inherited tendency to drug addiction was essentially a blood defect—the action of defective blood upon the mind organ. The action of alcohol and stimulating drugs was to provide something which the normal individual received adequately from his blood. He had met with a case of periodic craving for cocaine, and his explanation was that the blood underwent periodical changes which at certain times made the craving for stimulants difficult to resist, while at other times there was no craving at all.

Dr. O'Sullivan hoped that if Dr. Campbell's view of the causation of the nervous temperament was correct there might sooner or later be evolved a method of treating the fundamental cause of these addictions. Dr. F. W. Willway thought that prominence should be given to Professor Dixon's statement that drug taking in America had not enormously increased as a consequence of the withdrawal of alcohol, statements to the contrary effect were industriously circulated. Dr. Adams remarked that there was such a thing as a national physiology and psychology, and that drugs acted differently in different races just as in different individuals.

Sir William Willcox, from the chair, remarked that he did not know of any case in which cocaine had been used for murder, certainly not in this country of recent years, but a good many cases of suicide by cocaine had been brought to his attention. He had seen cases where people, such as nurses, who had had access to cocaine had taken enormous doses—40 or 60 grains by the mouth. It was possible to get hold of these cases in time—within an hour or two—when there was a good chance of recovery because cocaine was an unstable alkaloid and washing out the stomach with permanganate decomposed it. With regard to the production of convulsions by cocaine, there had been three fatal cases at his own hospital, following on the administration of cocaine to the urethra before the passage of a catheter. It was extraordinary how recklessly cocaine was used in former days by certain specialists in treating diseases—solutions of as much as 10 per cent. or even the solid powder were used. He had seen it freely applied to the mucous membrane of the nose. The wonder was that there had not been more fatal cases from the use of this drug. Dr. Copeland had referred to the formation of addiction habits by cocaine substitutes, but it was difficult to say which particular compound would lead to the formation of a habit. During the last two or three months he had seen three cases in which patients suffering from asthma had become mildly addicted to adrenaline, the same could be said, he thought, of a good many other drugs. It was difficult, therefore, to say that a certain chemical would not produce the drug habit. Only time would show. The pure cocaine habit with hypodermic use was very rare, generally the morphinomaniac took cocaine for a change. Cocaine was chiefly used in combination with another drug or as a temporary alternative.

Professor Dixon, in reply to Dr. Dale, said that he did not regard the frequenters of the cafés of cosmopolitan Europe as normal people at all. They were worn-out people, leading an artificial life, and were always in a state of gloom until they became intoxicated with one or other substance. These were the people whose nerve cells were lashed into activity by cocaine so that they lost their lethargy and became violently energetic for the time being. These were the people who took cocaine with avidity, they were neurotics, and had become so in consequence of the unhealthy and unnatural life they had been leading. In a normal person, leading an ordinary life, the result of cocaine-taking was very different, it was so distressing that he was not likely to have any desire to repeat the experience. It was really painful, and how cocaine could produce the unspeakable beatitude and the pleasures so extravagantly described by the writers who had witnessed its effects in Peru he could not understand. These effects could not have been got from cocaine, even drug addicts did not describe the effects in that way. Either the historians thought it correct to indulge in exaggeration or the coca leaves could not produce quite the same effect as the cocaine. Coca leaves brought over from Peru certainly produced no effect at all, but then Indian hemp brought over in the ordinary way also had no action, although sent in sealed tins from the Himalayas it appeared an absolutely different substance. It might be, therefore, that there was some other property in the coca leaves which did not survive export under ordinary conditions. With regard to the drug habit in America, this had been increasing for many years, independently of prohibition. The emotional condition in which the war left the people accounted there as in other countries, for some increase in drug addiction. He added, in conclusion, that it was a disgraceful thing that the *British Pharmacopœia* should set out a 5 per cent. solution for cocaine injections. The French *Codex* gave, he thought, a 1 per cent. solution for hypodermic injection, and nothing more than this was ever required.

BLOOD CHANGES IN PREGNANCY

A MEETING of the Section of Obstetrics and Gynæcology of the Royal Society of Medicine was held on October 2nd, the President, DR H RUSSELL ANDREWS, in the chair

DR J MARRACK read a paper on plasma proteins in normal and abnormal pregnancy Comprised in the paper were the results obtained by DR L J COETZEE from work in the Hale Clinical Laboratory of the London Hospital The plasma proteins of normal and pathological women were compared with those of patients suffering from conditions which affected the plasma protein The changes in plasma proteins in pregnancy, whether normal or abnormal, differed from the changes resulting from the injection of foreign proteins It was suggested that absorption of foreign proteins might occur in pregnancy, but that the normal protective response failed, especially in conditions of eclampsia Changes similar to those in nephritis occurred in pregnancy when there was evidence of kidney damage alone, but in the toxæmia of pregnancy and eclampsia the changes characteristic of renal damage were much modified DR Marrack supplied bibliographical references and showed tables of the fibrinogen, albumin, and globulin ratios in various conditions

The PRESIDENT read a short communication on an unusual retroperitoneal tumour in a multipara, aged 42 He had removed it at an operation believing it to be composed of fat, but during the removal a necrotic patch gave way and about two pints of dark, odourless fluid escaped, suggesting sarcoma The patient recovered, but three months later had a large mass in the right loin Microscopical examination of the original tumour showed the presence of spindle-celled fibrous tissue having the characters of fibrosarcoma, but the cells were arranged in well defined bundles and were uniform in size and shape The lobule was limited by a fibrous capsule, and the President regarded the tumour as a retroperitoneal fibro-lipoma, with a fibrosarcomatous focal area of histologically low malignancy

A clinical demonstration preceded the two papers and discussion

THE PRODUCTION OF CLEAN MILK

A MEETING of the London Association of the Medical Women's Federation was held on October 14th, the President, Miss M CHAMBERS, being in the chair

DR SYLVANUS WILLIAMS, in opening a discussion on clean milk and its production, pointed out that the milk industry had hitherto had little help or guidance from the medical profession in producing clean milk, but only those actually in the industry could fully appreciate the difficulties and work out their solution Since the establishment, under the auspices of the Ministry of Agriculture, of the National Institute for Research in Dairying in 1913 at Reading, the local farmers had been interested in the ideals there put forward The abolition of dirt in milk was a problem which must be approached from an economic standpoint Berkshire farmers had shown themselves receptive of the new ideas about asepsis, and six or seven years ago it was generally recognized that a better quality of milk was worth a better price After a considerable struggle the principle was established that farmers were entitled to charge more for clean milk Three grades of milk were at present available certified milk, bottled at the farm, Grade A tuberculin-tested milk, bottled by the dealer to whom it was delivered in sealed jugs, and ordinary milk Certified milk formed only 2 per cent of the milk supplied in New York at present, and it seemed unlikely that it would ever be possible in New York, or in this country, to supply it so cheaply as to create a large market Grade A tuberculin tested milk, however, could be produced at a charge of only 1d per quart more than that of ordinary milk In New York 2 per cent of the milk consumed was fresh 98 per cent being pasteurized The alternative to pasteurization was the advocacy of tested clean milk which could be drunk without treatment, but Dr Williams said that efforts to create a demand by doctors for such milk had been only moderately successful

MR S WHITLEY, chairman of the British Dairy Farmers' Association, emphasized the difference between the methods of production of clean milk and those of farmers of by old days these crude methods still persisted in some farms where no effort was being made at present to improve the quality of milk The steps in the production of clean milk were as follows in the first place the cowshed was kept clean and the cows washed and dried before milking began The milker put on clean overalls and washed and dried his own hands MR WHITLEY observed that formerly some used to wash their hands in the milk The old wide-mouthed open milk pails were now replaced by covered pails, and a lip on the cover prevented dust which had settled on the cover from falling into the pail The pail was weighed and the contents poured into a tin receptacle, in which the milk was cooled, churned, and sent in a sealed can to a retailer, who was compelled to have a Grade A T T licence Such precautions were worth the 15 to 20 per cent extra charge that the consumer had to pay Last year more than 100 farmers were producing higher grade milk The supply then was greater than the demand, but now, though more farmers were producing this milk, MR WHITLEY understood that the demand was greater than the supply Many farmers were only waiting to recognize the existence of this demand in order to start producing Grade A milk

In answer to numerous questions, DR SYLVANUS WILLIAMS stated that Grade A milk could be bought in London at various prices In hospitals and welfare centres a start might be made in creating a demand which would bring down prices St Bartholomew's Hospital was supplied with Grade A milk, and on investigating some complaints as to its keeping qualities it had been ascertained that the milk had been kept too hot—namely, at a temperature of 74° F, whereas it should be kept at 60° F He admitted the great variability of the price of milk in London districts, and said that the price of Grade A milk ought not to be more than 2d per quart in excess of ordinary milk there was no law to prevent dairymen from charging what they could get A solution of the problem of distribution had not yet been found

Reviews.

ANAPHYLAXIS

DR AUGUSTE LUMIERE's book on anaphylaxis[1] is an important contribution to medical literature Not that there is much in it which has not already been offered to the scientific world, for DR LUMIERE has been working at anaphylaxis many years and has published a great deal on this subject The book is valuable because it collects all these researches into one volume and expounds the author's views with a clarity which it is exceptional to meet with in books on this theme

There is a tendency for monographs on such problems of pathology to develop into dictionaries, to which it may be handy at times to refer, but wherein only the scholar is at home There is nothing of this atmosphere about DR LUMIERE's book, it is simply written, not overburdened with quotations and references, and is as readable for the unmitigated as for the expert

The general point of view with regard to anaphylaxis is not strange to pathologists in this country, but some of the conclusions and explanations cover new ground In brief, he holds that antigen mixed with the blood of a sensitized animal provokes a flocculation in the body fluids and it is these flocculi which are responsible for the manifestations of anaphylaxis The physical state and the chemical composition, of the antigen antibody complex determines anaphylaxis This flocculation mechanically stimulates the nerve endings of the endothelium of the vessels in nerve centres, and the accidents of hoc are more severe the more sudden this excitation The endothelium may accustom itself to this stimulation but abrupt stimulation of nerve centres provokes a vaso-dilatation or visceral vessels and a fall of blood pressure DR LUMIERE maintains that the modification in the composition of the blood met with in anaphylaxis [illegible]

[1] *Le Problème de l'Anaphylaxie* [illegible] Paris: Masson et Cie. 1924 (Demy 8vo, pp. [illegible] 40 francs)

a direct relation to the intensity of the shock These blood changes, such as leucopenia and altered leucocyte distribution, are the result of the phenomenon of osmosis and dilution of the blood and different involvement of blood cells The modifications originate from the vaso-dilatation provoked by the action of flocculi on the capillaries of nerve centres This vaso-dilatation accounts for the osmotic currents which determine retardation of capillary flow, which alter the distribution of blood cells and temporarily modify the physical properties of the serum

The principles which govern the prevention and treatment of shock may be easily deduced if the above hypothesis is accepted They consist in avoiding the formation within or introduction into the blood of any flocculent precipitate When shock exists a certain number of alkaline substances are known which are capable of dissolving the precipitate formed by the union of antigen and antibody Since the flocculi are not identical in all cases, a reagent capable of dissolving some precipitates may modify others Formulae for some of these solutions are given Other steps in treatment consist in diminishing the excitability of the vascular system by anaesthetics or depressants, in counteracting the reflex vaso-dilatation by such drugs as adrenaline, and in compensating for the altered distribution of the blood by intravenous injection of fluids

These are the main lines on which the author's thesis is expounded In a summary so condensed as this the connecting thread of the argument is not so easy to trace as in the narrative of the book The reader is greatly helped by the excellent arrangement of the book, the well spaced out paragraphs, and the lavish illustrations

INTERNAL SECRETIONS OF SEX GLANDS

The volume entitled *The Internal Secretions of the Sex Glands*, by Dr A Lipschütz, professor of physiology in Dorpat University, is the second edition of a book[2] published in German in 1919, the author originally intended merely to translate the first edition into English but he soon found that the advances in knowledge made during the last five years rendered it necessary to rewrite the whole Dr F H A Marshall of Cambridge contributes a preface, in which he summarizes the scope of the work as follows

> The reader will find in the pages a comparative and connected account of the endocrine function of the gonad so far as these are known in all groups of multicellular animal The importance of such knowledge has now become generally recognized and the subjects treated are of profound interest for zoologist and physiologists alike as well as for medical men psychologists and students of eugenics

The volume is well illustrated and the lists of references, numbering altogether nearly a thousand are very complete The predominating note is caution, for the author has examined all the available evidence, and has avoided hasty generalizations, distinguishing carefully between proven fact and attractive but unproven hypothesis This is in very pleasant contrast with much that has appeared on this subject Endocrinology as a whole has suffered much from inaccurate work but the endocrine action of the gonads has perhaps suffered most or all

Dr Lipschütz not only shows that the mode in which the sex organs regulate the development of the rest of the body is extremely complex, but presents evidence which suggests that it may very probably prove to be even more complex than we at present imagine It is therefore difficult to give any short summary of the most important conclusions arrived at in the book, but a few points of special interest to medical men may be mentioned The discussion of the actions of extracts of testicles and ovaries makes it plain that the results obtained both in feeding and with injection are extraordinarily contradictory The author quotes evidence that injections of testicular extracts produce a general stimulant action on man, but adds 'One can scarcely say that these experiments on men provide proof of a specific testicular internal secretion" Experiments on the effects of injecting testicular extracts into animals are, however, quoted which provide evidence for the existence of such a specific testicular secretion

The caution of the author in accepting evidence that extracts of the gonads produce an effect whatever, even when injected provides an amusing contrast to the confident manner in which commercial preparations of these glands are recommended for cures of half the known diseases On the other hand the favourable results of transplantation of ovaries or testicles are considered to be firmly established, and a full account is given of the production of intersexuality by the grafting of testicle into a female and ovaries into a male A description is given of the satisfactory effects obtained in Germany by transplanting human testicles into men castrated by war wounds One very curious case is mentioned in which the testicle of a normal man was transplanted into a confirmed homosexualist with the result that the latter was cured of his abnormal propensities and married within a year This seems to open up some interesting new possibilities for what might perhaps be called medico-legal therapy

A chapter is devoted to the subject of rejuvenation and an account is given of the work of Voronoff and Steinach The author maintains his habitual caution in dealing with the results reported but the evidence mentioned seems to show conclusively that the methods of both Voronoff and Steinach can produce remarkable rejuvenation (or rather regeneration) and that the effects may last for more than a year

The third edition of Dr Weil's book has been translated into English this year and published under the title *The Internal Secretion*[3] The translator apologizes that the volume is completely up to date because he has had the assistance of the author in editing the translation In it an endeavour is made to give a general account of the action of the organs of internal secretion in the space of 267 pages The method followed is to take each important physiological function of the body in turn and to discuss the way in which it is influenced by the internal secretion Half the book however is occupied by two chapters—one on metabolism and the other on growth and bodily form Carbohydrate metabolism is discussed without mention of insulin—an inexplicable omission The interest of the author however is centred largely on the influence of the sexual gland on metabolism and growth He has not attempted to give references for this would have been impossible in so small a work The general impression gained from its perusal is that a laudable attempt has been made to summarize existing knowledge regarding the action of the ductless glands on the body, but that the result cannot be regarded as wholly satisfactory, one reason being that endocrinology is still in a stage when definite statements can be made which will meet with general acceptance Furthermore this book deals especially with the sexual glands and their mode of action as organs of internal secretion this is even more uncertain than that of the other endocrine glands In default of really reliable evidence the natural tendency is to accept any that seem to support the most attractive hypothesis and hence a summary though it may be plausible and interesting tends to become rather unsound

SURGICAL PATHOLOGY

A good up-to-date textbook on surgical pathology as distinguished from the general pathology to be found in the ordinary textbooks of surgery has been a long felt want Some such books are good museum catalogues other are good discussions of *post-mortem* anatomy nearly all fail in that they do not describe in sufficient detail the naked-eye appearances of pathological changes in the living tissues Professor McFarland of Pennsylvania University has written a book on *Surgical Pathology*[4] which though excellent in many respects, rather falls between two stools It is too advanced for the average student and lacks

[2] *The Internal Secretions of the Sex Glands The Problem of the Puberty Gland* By A Lipschütz M D Cambridge Heffer and Sons Ltd Baltimore Williams and Williams Company 1924 (Demy 8vo pp xviii + 513 142 figures. 21s net.)

[3] *The Internal Secretions for the Use of Students and Physicians* By Dr A Weil Authorized translation of the third German edition by J Gutman M D Phar D F A C P London George Allen and Unwin, Ltd. 1924. (Demy 8vo pp xviii—267 no figures. 16s net.)

[4] *Surgical Pathology* By Joseph McFarland M.D. D.Sc. London H. K. Lewis and Co. Ltd. 1924. (Roy. 8vo pp. xii—701 no figures. £2 2s net)

a good deal of the simple general information which would be useful to those beginning to specialize in surgery, and it is to them that the book is especially addressed The author says truly that the stress of modern life tends to divert the mind from the path of leisurely scholarly attainment, and though few surgeons are likely to have time to read this book from cover to cover they will probably find it useful as a book of reference Breaking with precedent the author has felt himself free to proceed on his own lines, presenting old facts and theories, adding new ones, and criticizing their relative values He divides his book into three parts Part I deals with congenital conditions of surgical interest This is well arranged and gives a detailed description of developmental abnormalities It is useful to have under one cover all the information on this difficult and complex subject

Part II deals with tumours The classification followed is that devised by Adami, the subject is arranged under two main headings—of the simple blastomata and the malignant tumours It would seem to be a mistake to include all the epithelial tumours under the heading of malignant tumours

Part III deals with the general pathology of the various organs, and here some defects are to be found For instance, the pathology of the breast occupies more space than that of the whole of the alimentary tract, and the subjects of obstruction and strangulation are scarcely mentioned, the acute infections are not dealt with and the chronic only briefly It would seem that the author has not considered the pathology of shock, blood transfusion, anaphylaxis, and immunity to come within the scope of his book Nearly all the illustrations are borrowed, and some of the few which appear to be original are not well reproduced Perhaps the high standard of the first part has led us to expect too much The section on the mammary gland deserves special notice The author has some trenchant remarks on this subject, and "chronic mastitis" has no place in his vocabulary

RETINAL VENOUS THROMBOSIS

THE second of the Monograph Supplements[5] issued by the *British Journal of Ophthalmology* is a clinical study of 62 cases of retinal venous thrombosis followed over many years by Mr R FOSTER MOORE The investigation on which it is based was originally begun in 1913, when the author held the Lang Clinical Research Scholarship at Moorfields Eye Hospital, and it was his intention to have kept the patients under observation for not more than three years But the war intervened, with the result that, while some of the cases have been lost sight of, the course of the majority has been followed for a much longer period than was at first intended, and thus the records are very complete This research on a subject which the author has made peculiarly his own is, it is needless to say, a most careful and painstaking piece of work It can safely be asserted that no ophthalmologist and but few physicians can afford to be without a copy No abstract can do justice to it, but we may extract the following points from the author's summary

The outstanding cause is arterio-sclerosis In 70 per cent of the cases of tributary vein thrombosis the superior temporal vein was the branch affected After thrombosis of a vein has occurred an attempt to re-establish the circulation, either by development of new collateral channels or by canalization of the clot, is usually to be observed both processes may occur in the same eye, but though the circulation may eventually be re-established in large measure, the functions of the retina are not correspondingly recovered Haemorrhages in the retina are the rule, and in few cases does it ever become free of haemorrhage, exudation patches are common but pigmentary change is much rarer In about one-third of the tributary cases, central vision of 6/36 or better resulted, in central vein thrombosis the rule is that no useful vision is maintained

With regard to the visual fields, in tributary cases a sector-shaped defect does not occur, but some loss of [illegible] corresponding with the blocked vein is occasionally [illegible] In central vein cases the peripheral field is often, at [illegible] surprisingly complete, but later on a general or irregular contraction occurs In central vein cases it is usual for the tension to be less in the affected than in the unaffected eye in a few instances the reverse is observed, and these are probably cases in which acute glaucoma subsequently develops In tributary cases there is no difference in tension between the two eyes The study of this series confirms the view that high general blood pressure does not affect in any way the intraocular tension Acute glaucoma developed in none of the tributary cases

Of the cases in this series, 41·6 per cent were known to have developed eventually a gross cerebral vascular lesion, and the average duration of life after the onset of venous thrombosis was 5·8 years

It only remains to say that the monograph is illustrated by 31 charts of the visual fields and by 32 diagrams It is a work that must be studied in the original, for it is a most valuable addition to clinical knowledge of retinal venous thrombosis

SIR J C BOSE'S RESEARCHES

THE treatise by Sir JAGADIS CHUNDER BOSE, F R S, entitled *The Physiology of Photosynthesis*,[6] is really a monograph on a problem in physiological botany, and as such cannot receive more than a short notice in a journal primarily for clinicians The author describes in detail the various experimental methods whereby he has studied the evolution of oxygen by the living green plant (*Hydrilla verticillata*) All his methods are highly ingenious, especially those whereby electricity is employed in obtaining automatic records of such phenomena as the rate of production of oxygen, the intensity of light, the measurement of temperature, and the gain in weight by the plant through its synthesized carbohydrate Since only elementary mathematics are used to deal with the statistical data obtained, and most of the functions investigated have their curves constructed, the results of each experiment can be rapidly apprehended Sources of fallacy which could vitiate conclusions seem to have been carefully guarded against The theoretical principle of "physiological inertia" as affecting photosynthetic induction is referred to in an interesting manner when this subject is being discussed (p 87) The sixty illustrations are conspicuously clear No one interested in a typically modern experimental research into one of the fundamental activities of vegetable protoplasm will regret examining this work

The Scientific and Other Papers[7] of Rai Chunilal Bose Bahadur, C I L, I S O, M B, F C S, are the outcome of filial and avuncular regard on the part of J P Bose M B, for the papers are his father's, but they are dedicated to his uncle These are discourses on a very large number of the most diverse topics, from the chemistry of foods, toxicology, and pharmacology, through diabetes, small pox, and medico-legal problems, to paper making and the chemistry of matches Some of the papers were originally given as lectures Several have more than ephemeral interest, of such are the articles on diabetes in India, the prevention of small pox, "On the necessity for immediately restricting the free sale of poisons in Bengal", and on "Bhowanipore food poisoning case" It is not clear to for whom exactly these papers have been published, but for one thing, some of them were written as long ago from 1892 to 1907 The chemical, pharmacological, toxicological reports represent much excellent [illegible] work There is a full index The paper used for the is of poor quality, and there is about the binding "get-up" generally an indefinable air of amateurishness

THE ABUSE OF COCAINE

In a volume of about one hundred pages Drs JORE and FRANKEL have attempted to give an account of the history and present extent of cocaine abuse and of the physical and psychical effects it produces They say that before the war the cocaine habit was practically confined to the prostitutes of the large capital, and that it was only during the war that it became at all prevalent in Europe It is interesting to learn that excess in the chewing of coca leaves must have been frequent amongst the South American Indians, for as early as 1569 the Spaniards condemned the drug and later tried to stop its cultivation on account of the damage it did to the Indians

In the volume under review three stages of intoxication are described (1) The euphoric stage is associated with a true stimulation of the higher centres of the brain, the powers of sensation and psychic activity are increased (2) This is succeeded by a stage of intoxication, in which the feeling of general well being is changed to one of anxiety, often associated with delusions of persecution The frequent crimes associated with cocaine abuse are usually committed in this stage (3) Finally comes the stage of depression or reaction, during which there is general lowering of the functions of the higher centres of the brain, and the subject feels utterly exhausted both physically and mentally

The effects of cocaine resemble those of alcohol rather than those of morphine, for the cocainist is an extrovert he is confident of his own brilliance and seeks companionship to impress The aphrodisiac action of the drug is held to be an important factor in its abuse, this action, strongly marked in women, is much more irregular in men cocaine, indeed, often renders the male impotent The reason for this difference between the reactions of the two sexes is unknown

The book concludes with reports of numerous cases of cocainism The authors give an account of a subject upon which little reliable literature is at present available The book is, however, rather diffuse, and could have been improved by more careful editing It should be read in the light of the recent discussion on cocaine addiction of which a full report appears at page 765 of our present issue

NOTES ON BOOKS

THE Pickett Thomson Research Laboratory is affiliated with St Paul's Hospital, London it was completed in August 1922 We have received an elegant volume the *Annals of the Pickett Thomson Research Laboratory*[1] vol i No 1, July, 1924, which is offered to the public at 25s net It contains five contributions by Dr D Thomson the first three dealing with researches on the virus of variola vaccinia on the etiology of measles, and on the etiology of scarlet fever the fourth with researches on the best methods of detoxicating vaccines without destroying their antigenic properties and the fifth with the classification of germs by microphotography It does not appear that any of these papers have been previously published The first three contain a fairly comprehensive review of the present state of knowledge of these matters, together with an account of some personal research work The remaining contents of the volume consist of an abstract of a paper by Dr T N V Potts (Assistant M O H Newcastle) on the treatment and prevention of the oto rhinological complications of scarlet fever by vaccines, a short paper by Dr M Saint of Paris on the relation of agglutinins and antibodies to detoxicated vaccines, and some observations on the treatment of cases of gas poisoning (resulting from the demolition of gas shells) by the medical staff of T N Pickett et Fils The volume contains 216 pages and some excellent illustrations It is not clear to whom the information in these various papers is addressed Such a book as this cannot have a wide circulation, and one wonders why the authors of the papers herein contained have chosen this instead of the usual channels of communication with medical readers There exist many different learned societies to which pathologists are invited to submit their research work Such papers as these are then discussed and reported in the proceedings or made available to all through the monthly or quarterly journals of scientific societies Owing to the multitude of scientific journals a prolonged search is often necessary in order to trace information on any one of the nine different subjects dealt with in this one book Those who contribute to such a volume as this might well ask themselves whether they would not find a more extensive audience and also lessen the labours of their colleagues, if they took their material in the first place to special societies when their papers would be published in the various transactions in which their possible readers are accustomed to search

Professor ALFRED GROTJAHN's work on social pathology of which the third edition[2] has recently appeared is divided into two parts The first or special part which consists of seventeen chapters is devoted to the consideration of various diseases and their social significance The chapters on acute and chronic infections, sexual diseases, and prostitution, diseases of the skin, industrial intoxications rheumatism and nervous and mental diseases have been written by Professor Grotjahn, and the remainder, which deal with respiratory, circulatory and alimentary disorders, pediatrics gynaecology and obstetrics surgical diseases, cancer ophthalmology and oto rhino-laryngology have been contributed by Drs Lewinsohn, Salomon Wolff Hamburger, and Kayser The second or general part consists of six chapters all written by Dr Grotjahn in which he considers successively the social importance of the various groups of diseases the social value of medicine hygiene hospitals and other institutions and the qualitative and quantitative regulation of the propagation of the species

THE National Council for the Unmarried Mother and her Child has published this year its sixth annual report[3] It contains however, very little that is of general interest as it has been purposely curtailed in order to admit of the publication in pamphlet form of a special statement of the work of State and voluntary organizations for the unmarried mother and her child, with a view to its wide distribution among overseas guests visiting the British Empire Exhibition The report records with the greatest satisfaction the placing of the Bastardy Act on the Statute Book in 1923 although that Act contains only a small remnant of the bill prepared by the National Council The Legitimacy Bill and proposals for a bill dealing with affiliation orders are also referred to but the report is otherwise brief and unimportant

The thirty third edition of the Charity Organization Society's *Annual Charities Register and Digest*[4] provides a classified register of the various charities in, or available for, London Summaries of the financial receipts and expenditure in connection with various charities are supplied for the years 1920 to 1922 inclusive Special attention has been paid to the index of societies and charitable agencies and consequently the useful information contained in the book has been rendered even more accessible than hitherto The classification of charities adopted in previous years is retained generally the institutions being grouped according as they provide relief for such afflictions as blindness and deafness relief for sickness and permanent or temporary distress or in reformatories and other educational institutions, or agencies for facilitating employment and emigration

Messrs J and A. Churchill have issued in pamphlet form a short *Medical Guide to the Principal British Spas and Climatic Health Resorts*[5] This is substantially a reprint (with illustrations) of the health resorts section of the current *Medical Directory*, prepared under the editorship of Dr R FORTESCUE FOX. It includes also lists of hotels hydro- and other residential accommodation at the various marine and inland watering places

Smith's Physicians and Surgeons Visiting List for 1925[6] is a handy pocket volume including a diary on a week to each page, and 32 pages of information and tables useful to general practitioners Ruled pages are provided for obstetric and vaccination engagements and various memoranda The volume is well bound it contains a pencil and two pockets for loose papers, and a useful index

MEDICAL AND SURGICAL APPLIANCES

Warm Ether

Dr Francis E Shipway (London, N W) writes I have been using for many years an additional tap, T', to my warm ether apparatus for the purpose of giving a constant supply of oxygen with variable amounts of ether, chloroform, or mixtures of the two The tap T' in the position O directs all the oxygen

to the patient, by moving it clockwise oxygen is passed through the anæsthetic in increasing amount, until in the extreme right position all the oxygen passes through the anæsthetic (this would be chloroform in the illustration) This simple arrangement has proved very useful and makes the administration extremely easy

LUNACY AND MENTAL DEFICIENCY

Board of Control's Report

The tenth Annual Report of the Board of Control for the year 1923 has just been issued [1] The most striking statistical fact in this report is the very large number of notified insane persons under care in England and Wales on January 1st, 1924 The number is 130,334, showing an increase of 4,053 on that of the preceding year, and is the highest yet recorded This increase does not necessarily connote any increase in the incidence of insanity amongst the general population What factors are to be held accountable for its production the Board intends to consider in a future report, in the meantime attention is drawn to the exceptionally low death rate for the year in question—1,036 fewer than in the preceding year—a fact which partially accounts for the startling increase First admissions during the year totalled 18,934

Owing to the accumulation of cases in mental hospitals, the question of accommodation is rendered particularly acute The Board urges the necessity of a thorough consideration of this problem, but in the meantime draws attention to certain provisional remedies A fuller use of the powers conferred under Section 25 of the Lunacy Act of 1890, whereby patients may be sent from mental hospitals to Poor Law infirmaries, should be exercised Absence on trial and boarding-out, wherever practicable, should be allowed The provision of nurses' homes within the grounds or of hostels outside would not only increase the available accommodation, but would benefit the nurses themselves, as at present more nurses sleep in the institution than are necessary for its proper control It is recognized that local authorities are compelled to limit their expenditure owing to the widespread financial stringency, but the construction of separate admission hospitals and of detached villas for convalescent cases, where means permit, would relieve considerably the present congestion and be of decided benefit to the patients concerned

As regards diseases, there is a notable diminution in the incidence of tuberculosis as compared with the previous year, but this still remains high (seven or eight times greater than in the general population, in spite of recent reductions)

[1] Board of Control Tenth Annual Report HM Stationery Office Imperial House, Kingsway, W C 2 Is 6d net

Various theories have been put forward to account for the state of affairs mental and physical peculiarities of patients, dietary deficiency, intramural wind infection understanding of the relative potency of these factors in production of the disease is very necessary There has marked reduction in the incidence of dysentery and its fatality rate Thirteen cases of pellagra were notified during the year, this disease was responsible for 10 deaths—9 amongst patients and 1 amongst the staff In recent years there been a considerable reduction in cases of general paralysis and a corresponding fall in the number of deaths from the disease The earlier recognition and treatment of syphilis partly accounts for this reduction in incidence, but it must also be borne in mind that previous to the systematic use of facilities for accurate diagnosis of the disease, an appreciable number of cases were erroneously regarded as general paralysis Consideration is given to the unfortunate mental sequelæ of encephalitis lethargica The Board has been in consultation with the Minister of Health on this matter, and it is hoped to formulate better means for studying, treating, and preventing these post-encephalitic mental conditions

There is a considerable number of patients at present in mental hospitals who could be more suitably dealt with in institutions for mental defectives Such institutions are all too few, however, and urgently require to be supplemented

Much remains to be done if continuity of care is to be secured for all mentally defective persons who cannot take care of themselves The full benefit of the Mental Deficiency Act as regards the prevention of suffering, crime, destitution, inebriety, and disease cannot be secured until the provisions of the Education Acts dealing with mentally defective children are brought into complete operation Although the powers and duties of all local authorities under the Mental Deficiency Act are the same, the Board of Control indicates how varied is the quantity and the quality of the work undertaken In some urban centres there is the closest co-operation between the local education authority and the committee for the care of defectives, and the numbers of mental defectives have been ascertained, the great majority of whom are in special schools In other centres such co-operation is lacking There is no methodical inquiry into the number of mentally defective persons, beyond those especially brought to notice The benefits afforded by the Mental Deficiency Act are not being utilized

The number of defectives ascertained for the year 1923 was 35,413, as compared with 25,470 for the previous year This increase shows an improvement in the activities of the local authorities, but there is still ground for believing that local authorities are still in ignorance of many cases of defect in their districts Authorities are urged to make more use of the powers conferred in Section 30 of the Act, allowing cases under guardianship It is also suggested that Section 7 of the Act be amended so as to allow of the transfer of a defective from an institution to guardianship

The very great difficulty of treating large numbers of violent and dangerous defectives is readily acknowledged The former methods of certifying such patients as insane and transferring them to mental hospitals did not prove satisfactory The Board realizes the necessity of facilities for isolation, and "it is significant that the opportunity afforded for solitude is greatly appreciated by the patients themselves" The co-operation of the Central Association for Mental Welfare in all questions relating to mental deficiency is gratefully acknowledged

The report refers to the abandonment of the Mental Treatment Bill, whose provisions have had the particular attention of the Board, who finds a "general consensus of opinion in favour of allowing early cases of mental disorder to be received for treatment for a period without certification under proper safeguards, and of extending to public mental hospitals the power to receive voluntary boarders" As recorded lately in our columns, special powers authorizing the reception and treatment of voluntary boarders at the Maudsley Hospital were granted under the London County Council Act of 1915, and the extension of similar powers to public mental hospitals cannot but be fraught with the greatest benefit to the mentally afflicted

SATURDAY, OCTOBER 25TH, 1924

THOMAS LINACRE 1460–1524

On October 20th, 1524 Thomas Linacre the founder of the Royal College of Physicians of London died at his house in Knightrider Street and was buried in St Paul's Cathedral. Four hundred years have elapsed since that event but the anniversary of his death cannot be allowed to pass without some reference to the great and lasting benefits his labours conferred upon this country in his capacity as an enlightened physician and as a scholar of European renown.

Born at Canterbury he was educated at the monastery school of Christ Church in that city under the guidance of William Selling, who was one of the first in this country to acquire and spread the knowledge of the Greek tongue. In 1480 Linacre removed to Oxford, and under Cornelio Vitelli applied himself to the study of Greek. In 1484 he was elected a Fellow of All Souls, and in 1485 he travelled to Italy for the purpose of perfecting himself still further in Latin and Greek. Arrived there, he visited Bologna where he availed himself of the instruction in Latin of Politian, and Florence, where he came under the influence of Chalcondylas, who refined his already extensive knowledge of Greek. He then repaired to Rome, Venice, and finally to Padua where he took the M.D. degree of that university with great applause.

His visit to Italy exercised a profound effect upon his mind. He came to that country thirty-two years after the Greek Empire at Constantinople had ceased to exist, and he found the Italian universities full of students striving to acquire the inestimable results of the revival of the Greek spirit which had been brought to Italy by the refugee Greek scholars. He was impressed with the manner in which facilities were afforded in the universities for the prosecution of the quest for knowledge in all its branches. Padua was at that time nearing the zenith of its influence and it was there that he first conceived the idea of devoting himself to the study of medicine. His main purpose in visiting Italy was the acquirement of scholarship and with his rich endowments in this intellectual sphere he could have had little difficulty in performing the exercises necessary for the medical degree since they were purely scholastic and only required a knowledge of the ancient medical authors. He must have compared these intellectual centres in Italy vibrating with life, with the sterile conditions existing at Oxford where the barren scholasticism still held sway. While preparing for his degree in medicine at Padua he had observed the attention paid to that subject. The care bestowed upon the study of medicine in Italy made an indelible impression upon his mind and when in after years he resolved to improve the condition of physic in his own country it was after the Italian model that he shaped his College of Physicians.

On his return from Italy, about the year 1487 Linacre resided at Oxford where he continued his studies in classics and medicine, and it was during this period of his life that he devoted himself with his friends Grocyn, William Latimer, and Erasmus, to the work of promoting the revival of letters in this country. In 1501 he was summoned to the Court to undertake the dual duties of preceptor and physician to Prince Arthur and became physician to Henry VII and Henry VIII. About the year 1509 Linacre entered the Church and for the remainder of his life devoted his attention to the study of theology and to his duties as a cleric. It was not until 1518 that he was able to put in operation his cherished scheme of founding a College of Physicians for the purpose of promoting and controlling the activities of those who were engaged in the practice of medicine. At that time the conditions in England regarding the practice of medicine were deplorable. No attempt to control the practitioners in the country was effective for the Act of 1511 giving power to bishops or their vicar general to license those wishing to practise medicine had proved of little use. The country was flooded with ignorant men who had had no training in medicine and who practised their calling without let or hindrance. Linacre desired to elevate the profession of medicine and to secure for the benefit of the country men who had been properly trained and who were armed with learning and knowledge of medicine. His aims were realized on September 23rd 1518 when King Henry VIII granted a charter to Thomas Linacre and five other physicians to form a College of Physicians for the purpose of electing other physicians who in the opinion of the College were worthy of that distinction. The charter at first gave the College power to regulate the work of all physicians in London and seven miles around but in a little time its provisions were enlarged to include control over all who practised medicine in England with the exception of those who were doctors of Oxford or Cambridge. Thus through the inspiration of Linacre came into being the Royal College of Physicians which has existed now 406 years. Throughout its history the spirit of Linacre has exercised a profound influence over its character. Linacre was a great scholar and it was his desire that scholarship should go hand in hand with medicine. Modern developments in medicine have rendered this difficult or even impossible but through all the changes the College of Physicians has always been closely associated with high intellectual attainments, which were so prominent in the founder.

Linacre's influence upon medicine did not end with the foundation of the College of Physicians. He established two lectureships at Oxford and Cambridge called after his name and although they have not exercised any considerable influence over the course of medicine they are nevertheless evidence of Linacre's desire to improve medical teaching and practice. As the great example of the scholar-physician Linacre stands pre-eminent and we must never forget that it was largely through his translations of Galen into elegant Latin that physicians were led to study that giant of the Middle Ages and when they studied they soon began to doubt. Then came Vesalius Harvey and Sydenham and the teaching of mediaeval times was swept away never to return. For all that Linacre accomplished for medicine we commemorate to-day with deep respect and grateful thanks the four hundredth anniversary of his death.

THE PANEL CONFERENCE

At the Annual Conference of representatives of Local Medical and Panel Committees which was held last week the matters under discussion were of less immediate importance than in recent years and did not give rise to any serious controversial issues. From the full report which appears in the SUPPLEMENT it will be seen, however, that at least two questions of interest to the profession occupied considerable attention

One of these was the case in which a heavy penalty had been imposed by the late Minister of Health on two Lancashire practitioners, and the other was a point of public importance in connexion with evidence to be given before the Royal Commission on National Health Insurance

In the penal case referred to no one was concerned to defend the practitioners' actions which were called in question, but the report of the official committee of the Ministry of Health which inquired into the facts, disclosed, and even emphasized, a number of considerations which made the offence seem less heinous than at first sight it appeared to be The Conference was evidently much disturbed by the situation which the action of the Minister has occasioned, and passed unanimously resolutions of protest with regard to two points which seem to be of general concern, and can scarcely be allowed to rest where they are at present, in spite of the evident desire of the Ministry not to reopen them The correspondence clearly discloses the fact that the penalty—a "fine" of one thousand pounds—was to some extent inflicted in respect of offences which the Minister assumed had been committed, although no evidence of them committal was produced, even after most assiduous attempts to discover such evidence As one of the resolutions passed by the Conference says, "it is contrary to the principles of English justice to assume offences over and above those proved at the inquiry and to inflict any penalty in regard to such unproved offences", yet it appears clear, even from the last letter from the Ministry itself, that this is what has been done

The Conference further protested against the action of the Ministry on an important point of procedure Regulations have laid down, in agreement with the profession, certain rules and machinery by which alleged offences are to be investigated The Insurance Committee concerned, having followed the required procedure, came to certain conclusions It must be recognized that the Minister, charged by Parliament with the administrative duty of seeing that the medical service is efficient, may properly take independent action in a disciplinary case if he considers such action judicious In the case in question, however, the Minister, who was in the position of the judge who must finally pronounce judgement, caused a letter to be written asking or directing the Insurance Committee to revise and alter the conclusion to which it had come This action appears altogether indefensible and even outrageous It seems evident, on the facts of the whole case, that any Minister of Health who may be in office as the result of the general election may properly be asked to review the judgement of his predecessor

Another important matter that was the subject of discussion [illegible] accommodation, but evidence should be given before the Royal [illegible] present more fully with regard to the administration necessary for its proper approved societies with a view to the widespread financial No doubt many committees are composing administered by State organizations the admission practitioners by them insured plants are bad cases, where us imperfections in this patients pending present con- however, be assumed that administration concerned all such complaints rises, there unded, and in any case, as was pointed out [illegible] Conference, it is by no means certain that it is [illegible] for the medical profession, as such, to concern itself [illegible] this matter, so long as medical benefit—including all such additional benefits as in fact if not in law, are of the nature of medical benefit—is entirely separated from approved society administration This is the fundamental necessity, and it may well be that within their own sphere approved societies, subject to certain general requirements, would do the work of administering sickness and other cash benefits more efficiently and sympathetically than would any organization under State auspices and run by Government officials The decision of the Conference was that this, as well as other points connected with the evidence to be given before the Commission, should be considered by the Insurance Acts Committee, and that if possible opportunity should be given to Panel Committees and to Divisions of the British Medical Association to consider the memorandum of such evidence before it was finally agreed upon

FOOT AND MOUTH DISEASE

During September nine outbreaks of foot-and-mouth disease were confirmed in England, and restrictions were still in force in six districts The cost of the outbreak so far is about £3,500,000, and over 200,000 animals have been destroyed The American outbreak, which started in February last, has, according to Dr Mohler, chief of the Bureau of Animal Industry,[1] been practically stamped out The policy adopted was that of prompt slaughter of infected herds, cleansing and disinfection of infected premises, and compensation of owners for animals and property destroyed In the more settled areas eradication was promptly effected, but difficulties were met with in the inaccessible and poorly fenced range country, Dr Mohler, however, expects that the disease will have completely disappeared by the end of this year The outbreak has cost America over £1,000,000, and 108,000 animals have been slaughtered The methods adopted do not differ from those in use in this country, except in degree They were undoubtedly more drastic in their operation, mainly because of the existence of the highly organized Bureau of Animal Industry—a body which has no counterpart in Great Britain It is stated in the October issue of *Veterinary Medicine* (Chicago) that "when the results in the settled portions of California are compared with the efforts that have been put forth and the results attained in England during the past year in combating the present outbreak of foot-and-mouth disease in that country, the excellence of the American method can be better appreciated by contrast In England the disease has persisted for more than a year and eradication is not in sight, although the cost of the work has been three times the cost of that in the California outbreak and twenty times the cost of complete eradication in the settled portions of the state There is no question but that our Bureau of Animal Industry could have eradicated it in that period at any time since its appearance in England or Scotland, if it could have the same co-operation and support from the authorities and the people that it had in California" Even after discounting the influence of the naturally optimistic American spirit, it would seem that their criticism, although exaggerated, is not without truth, and it is well to know the opinion of other countries In a "slaughter" policy of eradication half-measures are futile and expensive, but we must also realize that such a policy is tolerable only in the almost complete absence of any real scientific knowledge of the etiology of the disease We have reported at various times the progress of [illegible] on foot-and-mouth disease abroad Early this year Löffler and Dahmer described what they considered to be the [illegible] organism—a minute ultra-microscopic microbe producing cultures the size of a red blood corpuscle A Government commission was appointed to investigate their [illegible]

[1] *Journ Amer Vet Med Assoc*, 1924, p 751

in an interim report[1] Professor Luhrs states that so far both cultural and experimental inoculations have been without positive results. Frosch and Dahmen were not present at the meeting to which the report was made, and Luhrs gave few details. Frosch and Dahmen, however, in a written reply, told that not only is the report by no means final, but that it is premature, and they claim confirmation of their work by Ruppert of La Plata, who has conducted his experiments on the basis of their published work. Although its specific nature is now disproved, we are not yet in a position to accept the Frosch-Dahmen bacillus as the cause of the disease. The report in the German journals, that the commission had confirmed their results, was apparently due to a misunderstanding. Meanwhile Vallée has given an account of recent French work on the disease. His efforts have been directed towards the solution of the immunization problem. He finds that blood drawn from recovered animals about the twelfth to fifteenth day of the disease has not only a certain curative action but gives almost complete immunity to susceptible subjects for from six to eight months. Large doses are necessary and the protection is specific for only one strain—or when there are two. The most recent and most interesting French work, however, has been directed toward obtaining a sensibilized anti-aphthous vaccine, which without causing a generalized infection, results in only a limited local one which is accompanied by an active immunity. The fact that the red cells absorb the virus—exactly how is unknown—and so render it more controllable, has been utilized. An intradermal inoculation of 0·6 c.cm. of red cells drawn from cattle cured of the disease with all untraced virus eliminated causes a cutaneous reaction without aphtha and gives a strong immunity. It is hoped by an extension of these experiments to be able to use a method hitherto considered too uncertain or too risky, and to be able to elaborate some technique whereby they can accurately estimate the exact virulence of the virus. The etiology of the disease will be discussed at the November meeting of the Berlin Micro-scopical Society, when the members of the commission and Frosch and Dahmen will be present.

SPIRITUAL HEALING MISSIONS

THE daily press has recently contained accounts of spiritual healing missions held by Mr J. M. Hickson at Frizinghall Parish Church, Bradford, and at St Michael's Church, Paddington. The Bishop of Bradford (Dr Perowne) took part in the mission at Bradford, where some 1,200 or 1,300 people seem to have been treated by the laying on of hands. According to newspaper reports some six or eight patients, suffering from diseases of long duration, have been benefited by the mission, and at the end of this month a thanksgiving service is to be held at Frizinghall, when a full statement of the healing results will be given. The cases in which improvement is said to have taken place are an elderly woman with rheumatoid arthritis, a domestic servant whose "right arm had been paralysed from birth," two cases of "spinal paralysis," a woman who had been blind for five years and now asserted that she could see a little, a woman with "paralysis of the left side for over a year," a young woman who had suffered for ten years from hysterectomy," and a man who had been dumb for two years. The Bradford mission seems to have been very well organized in the matters of transport, commissariat, and police control, and is described in the local press as having profoundly stirred religious thought in the city. One paper mentions the "ecstasy of the cured," and then testimonies to the power of the mission. We have called attention on former occasions to some of the dangers attached to the emotional appeals of these spiritual healing missions. Dr Otto May, in a letter to the *Times* on October 20th emphasizes the emotional element in the cures and points out the effect of suggestion on functional disorders and on the functional element in disease. While it is no doubt right that the mental element should never be ignored in the treatment of even organic disease, wholesale suggestion of cure must as Professor F. E. Wynn has pointed out in a letter to the *Yorkshire Post*, in fact be cruelty or disappointment on ignorant sufferers from really incurable maladies. We are glad therefore to note that the Bishop of Chichester (Dr Burrows) warned his Diocesan Council, which was addressed by Mr Hickson, that participants must be properly prepared spiritually, to be ready to accept disappointment." Clearly a medical investigator of all claimed cures would require more definite diagnoses than those we have quoted from the newspapers and it is impossible to expect medical men to accept as evidence statements entirely unsupported by though capable of [illegible]. And when we read of "cures" in connexion with such missions we are inclined to think that the organizers might read with advantage Dr Quinton's *Confessions of the Specialist* in the fourth series of Froude's Short Studies on Great Subjects.

HYGIENE IN GIBRALTAR

GIBRALTAR in actual extent of territory probably the smallest of our colonies has an interesting and instructive record of sanitary legislation and of the health of its civil population. The density of population and the housing conditions are such as might be expected to give rise to a very high incidence of disease and mortality; for according to the annual report on the health of Gibraltar for 1923,[1] 1,316 of the 3,420 families who constitute the civil population of 17,346 live in one room dwellings and in a city area of little over 104 acres. Of the 1,316 families in one room dwellings are families of six and 1,3 are families of more than six persons, while the situation as regards families in two-room dwellings is only a little better, for the highest number (181) among the 846 in such dwellings are families of over six members. Further, it appears that 10,000 Spanish and 1,500 British subjects come into Gibraltar daily from the neighbouring Spanish town, La Linea. This constant traffic is extremely apt to introduce infectious disease into Gibraltar, and, in fact, most of the small-pox epidemics which have occurred in the fortress were traced to foci of infection in Spain or Morocco, both being separated from Gibraltar by only a narrow strip of land or sea. Notwithstanding these detrimental health conditions the standard of public health in Gibraltar has been maintained at a very high level for many years, this has been due in a great measure to the efforts of a succession of army medical officers with a wide reputation as sanitary experts who have held the appointment of medical officer of health. It was in the nineties of last century that the then medical officer of health undertook the task of effecting important alterations in the civil habitations and crowded blocks of one- and two-room dwellings with a view to introducing light and air into them and providing suitable sanitary accommodation for the occupiers. Among other measures, by-laws, based on the model by-laws of the Local Government Board, were drawn up, and in 1892 the present form of annual report on the public health was inaugurated. The result of these measures was a marked permanent fall in the mortality rate from a figure considerably above 30 to one considerably below 20 per 1,000. During the last ten years only on one occasion—the influenza year of 1918—has it reached that figure. The average for 1913-22 was only 16·9 per 1,000, for the previous ten years 26·15, and for 1923 16·95. These figures represent more or less [illegible]

crude death rates for the past thirty years The birth rate for 1923 was 22 57 per 1,000, and the infantile mortality 109 5 per 1,000 births The average zymotic mortality for the last ten years was 1 31 per 1,000 of population, but in 1923 it rose to 1 84 owing to a somewhat extensive epidemic of scarlet fever, a disease of rare epidemic occurrence in Gibraltar Isolation could only be carried out partially, but the cases were comparatively mild, as is the general experience of scarlet fever in tropical or semi-tropical climates Most of the diseases which can be controlled by sanitary measures or require sanitary investigation are notifiable They include, for example, gastro-enteritis, tuberculosis, pneumonia, venereal disease, dysentery, Mediterranean fever, and others, in addition to the acute infectious diseases, and the fact that these are notifiable gives Gibraltar a considerable sanitary advantage over many other communities Pulmonary tuberculosis caused the greatest number of deaths amongst them, amounting to about one-third of the total deaths due to the notifiable diseases in 1923, but the death rate was only 1 3 per 1,000 of population, as compared with 1 62 for England and Wales Considering the overcrowding and housing conditions this must be regarded as somewhat remarkable, and, apart from general sanitary measures, is probably due to the excellent organization of a "destitute sick and tuberculosis scheme," subsidized by a grant from the Colonial Government Food and milk are supplied to the destitute and sick poor, home visits are paid by a nurse, and accommodation is provided in a home for early cases of tuberculosis School hygiene is also carefully supervised, and a soup kitchen was started last winter to supply soup in the school interval to children of the poor There is also a child welfare centre, which not only advises and instructs mothers in the care of children, but has also distributed milk and other medical comforts to families of the unemployed The City Council of Gibraltar may with reason congratulate itself on the good results of its public health department and on such excellent auxiliary schemes as these Neighbouring cities, such as Malaga and Cadiz, have shown very different health results, so that the climate of the south coast of Spain can scarcely be claimed as a factor in diminishing the incidence of tuberculosis and other preventable diseases in a crowded city like Gibraltar

SOCIETY OF MEDICAL OFFICERS OF HEALTH

THE Society of Medical Officers of Health, now entering upon its sixty-ninth year, held its annual dinner at the Hotel Cecil, London, on the evening of Friday, October 17th The new president, Dr Robert A Lyster, who had delivered his presidential address at the headquarters of the society earlier in the day, took the chair, and was supported by many well known members of the medical profession but politicians, owing to the coming election, were absent Besides the after-dinner speakers those present included Sir William Hamer, medical officer of health for the County of London, Mr W H Savery, chairman of the Housing Committee of the City of London Corporation, Professor Waller S Leathers, of the Vanderbilt University, Dr Herbert Jones, Dr Lustace Hill, and several other past-presidents of the society, Dr H B Brackenbury, Chairman of the Representative Body, and Dr Alfred Cox, Medical Secretary, of the British Medical Association, and Sir Dawson Williams, Editor of the *British Medical Journal* The toast of prosperity to the Society of Medical Officers of Health was submitted by the Bishop of Winchester (Dr F T Woods), who welcomed this opportunity of proposing the health of the health preservers of the community, and thus, as it were, offering 'a cock to Aesculapius" He urged the need for a wider and keener spirit of helpfulness within the Christian Church in aiding the medical service of the country the aim of all should be to make England not only fit for heroes to live in, but to make heroes fit to live in it The president of the society, in his reply, said that no body in the world would welcome more heartily than theirs the powerful aid of the Church in promoting and stimulating the highest ideals of the public health As a society they had no politics, and he wished to make it clear at the present juncture that any political party that came into power would find in the society a machine able and willing to give expert advice on public health matters He noted with regret that the proportion of brilliant men entering the public health service was much smaller to-day than in the past, the causes of this serious decline ought to be examined, for in the vast field of preventive work lay a great future for the public health branch of the medical profession The toast of the Ministry of Health, proposed by the honorary treasurer, Dr G F Buchan, was acknowledged by Sir Arthur Robinson, permanent secretary of the department, who mentioned with regret that three consecutive elections at this season of the year had prevented the reigning Minister from responding to this toast—and civil servants should be neither seen nor heard The health of the guests was proposed by Dr Harold Kerr, medical officer of health for the city of Newcastle-on-Tyne Lord Dawson of Penn, in his reply, complimented the society on its remarkable growth, and urged it to aim at bringing the general practitioner more and more into preventive work The toast was acknowledged also by Sir Humphry Rolleston, Bt, President of the Royal College of Physicians, Sir Francis Champneys, Bt, Chairman of the Central Midwives Board, and Mr H J Waring, Vice-President of the Royal College of Surgeons The health of the president was proposed by Dr Lockhart Stephens, president of the Southern Branch of the society, and Dr Lyster replied

THE HOUSE OF LONGMANS

IN the October number of the *Edinburgh Review* Mr Harold Cox records and celebrates the two hundredth anniversary of the foundation of the publishing house of Longmans It was already an old firm when the *Review* first appeared in 1802 under the auspices of Constable and Longman, to be afterwards carried on by the latter firm alone But the house, if not the firm, is really older than 200 years, for the first Thomas Longman bought a going concern from William Taylor, at the sign of The Ship in Paternoster Row, in 1724, where Longmans is still carrying on the business Taylor must have had a valuable connexion and stock-in-trade, since Longman paid what was then the very large sum of £2,282 9s 6d for it The odd shillings and pence suggest that he bought it on a valuation The fact that Taylor was the publisher of the first authentic edition of Robinson Crusoe shows that he was of good standing in the trade There are no doubt commercial concerns still in existence which are as old or older than the house of Longman, but it is exceptional indeed for any firm which has existed for two centuries to be able to say that any of its partners are the direct descendants of the founder Yet it is the fact that three Longmans of the sixth generation are now active members of this celebrated firm Its history is bound up with that of English literature since 1724 Longman was one of a number of publishers who were jointly responsible for the production of Johnson's dictionary, and the sufferings of many generations of schoolboys were associated with Lily's Latin grammar, despite which book, or with its help, some of them acquired their first knowledge of classical literature Buckley and Longman together acquired by purchase from the patentee the Royal grant and privilege of printing that celebrated work, in the preparation of which Colet and Erasmus had no small share It appears probable, too, that from the Longman the second had some interest in the produc-

of the *Times* Coleridge, Wordsworth, Walter Scott, Southey, Tom Moore, and Byron all entrusted the publication of their poems to this firm, although Byron soon transferred his works to John Murray Macaulay, Lecky, and, indeed, a majority of the great writers of the nineteenth century, had their books published by Longmans, including some of the best known writers of fiction, such as Rider Haggard and the author of *Dr Jekyll and Mr Hyde* and a few artists such as Andrew Lang Mr Harold Cox reminds us that *Gray's Bratony* was and is published at the sign of The Ship, but he omits to mention *Quain's Anatomy* one of the important medical works which bore Longmans' name on their title pages One of these is *Quain's Dictionary of Medicine*, and at the present time four pages of their catalogue are filled by the titles of medical and surgical works, although the business of medical publication is now largely in other hands The present firm may claim an antiquity beyond 1724 for in 1800 the business of the then house of Rivington's, which dated from the very early years of the eighteenth century was transferred to it, with all its associations, and including that valuable and ancient periodical, the *Annual Register*

THE HARVEIAN FESTIVAL

THE Harveian Festival of the Royal College of Physicians of London consists of a short series of quiet and friendly ceremonies on St Luke's Day, of which the centre and chief is the Harveian Oration, which was delivered this year by the Regius Professor of Medicine in the University of Oxford The oration has a history of over two centuries and a half, and we must admire the grace and ingenuity with which orator after orator has succeeded in finding a new subject, or a new aspect of an old subject Sir Archibald Garrod succeeded once more for though we have heard much of the debt of medicine to science we have seldom been reminded of the debt of science to medicine The oration and dinner were attended this year by the distinguished French physician Professor Calmette who was presented with the Weber Parkes Medal Dr Achard Permanent Secretary of the Academie de Medecine of Paris, by which British representatives were so cordially entertained at the celebration of Jenner and Sydenham and Professor Chauffard who returned thanks for his colleagues at the Harveian dinner Other guests at the dinner were Lord Sumner, who responded to the toast of the guests, the Dean of Christ Church, Sir Arthur Stanley G B E, Dr G L Gulland, Professor of Medicine in the University of Edinburgh, and Dr T K Monro his colleague of Glasgow, Sir John Bland Sutton, President of the Royal College of Surgeons of England Dr L W Amies Walker, Dean of the Medical School of Oxford University, and Sir Leonard Rogers, Moxon Medallist

THE SADLIER SERMON

AFTER a lapse of many years the annual Sadlier sermon was delivered in the presence of the Lord Mayor of London on St Luke's Day October 18th, in the Church of St Marylebone, by the rector, Canon S G Ponsonby Dr William Croone, a Fellow of the Royal College of Physicians, originally designed a plan for two annual lectures to be delivered, one before the College of Physicians the other before the Royal Society together with a sermon to be preached at St Marylebone After his death in 1684 it was discovered that his will contained no provision whatever for the endowment of these lectures His widow, a daughter of Alderman Lorimer of the City of London who subsequently married Sir Edwin Sadlier, Bt, fulfilled Dr Croone's intention by devoting a portion of her estate for the provision of the annual lecture, now called the Croonian Lecture," and the sermon In the course of last year the Charity Commissioners approved a scheme confirming the provisions of the will, and empowering the trustees to make grants to augment the income of other lectureships in connexion with the Royal College of Physicians The proceedings at the service on October 18th included a lesson taken from Ecclesiasticus xxxviii, commencing with the word "Honour a physician with the honour due unto him for the uses which we may have of him" Canon Ponsonby opened with an account of the origin of the Sadlier sermon, and next described the character and attainments of St Luke as recorded in the New Testament and in documents of the early Christian era He then passed to the consideration of Thomas Linacre, founder of the Royal College of Physicians, and celebrated scholar physician, and divine His Latin translation of Galen was said by Erasmus to be even more elegant than the original Greek The preacher described the arms granted to the College in 1540 with the representation of a sick man stretching out his arms toward an arm coming from above and in conclusion referred to the marked and increasing recognition of the power of mind over matter that had characterized the last fifty years He added that there was no question of substituting spiritual healing for medical ministration, though perhaps there had been some confusion of thought on the part of those who did not understand that physicians had always attributed their successes to the spiritual power working through them They had always conveyed hope and healing to the sick and comfort and consolation to the dying as well as material medical treatment

---

THE first social evening of the session of the Royal Society of Medicine was held on October 16th The new president, Sir StClair Thomson received the guests in the library where refreshments were provided and interesting exhibits were on view Dr W T Grenfell C M G of Labrador delighted later the large audience with a detailed account of his work

---

THE Mitchell Lecture before the Royal College of Physicians of London will be given by Sir StClair Thomson at the College on November 6th at 5 p m The subject of the lecture is tuberculosis of the larynx and its significance to the physician

THE GENERAL ELECTION

NOMINATIONS for the forthcoming general parliamentary election took place on Saturday October 18th, when the following medical candidates were duly nominated

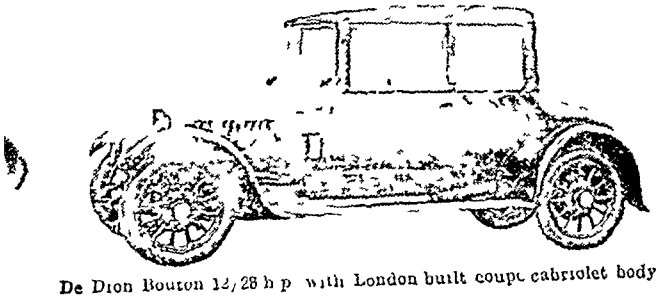
The Right Hon C Addison (Lab) Hammersmith South.
Dr Ethel Bentham (Lab) Islington East
Sir George Berry (C) Scottish Universities
Sir John Power Bradford (C) } University of London.
Dr F G Burnell (Lab) }
Dr E G Graham Little (Ind) }
*Dr W A Chapple (L) Dumfries
Dr Stella Churchill (Lab) Hackney North
Dr P Dunstan (Communist) Birmingham West
*Dr Walter E. Elliot (C) Glasgow Kelvingrove
*Dr F E Fremantle (C) St Albans
Dr O Gleeson (L) Portsmouth North
*Dr L Haden Guest (Lab) Southwark North
*Mr Somerville Hastings (Lab) Reading
Sir Henry Jackson (C) Wandsworth Central
Sir Richard Luce (C) Derby
Dr J J Lynch (Ind Lab) Walsall
Dr I H MacIver (Lab) Argyll
Dr R O Moon (L) Oxford
Dr H B Morgan (Lab) Camberwell North West
Dr Joseph Robinson (Lab) Stretford
Dr A Salter (Lab) Bermondsey West
Dr Laura Sandeman (C) Aberdeen North
*Dr G E Spero (L) Stoke Newington
Dr T Watts (C) Manchester Withington.
*Dr J H. Williams (Lab) Llanelly
*Lieut Colonel T S Beauchamp Williams (Lab) Lambeth, Kennington

Candidates who sat in the recent Parliament are indicated by an asterisk

Professor Thomas Sinclair (C), the representative of Queen's University, Belfast, in the last Parliament has been returned unopposed

THE OLYMPIA MOTOR SHOW.

CONCLUDING REVIEW FROM THE MEDICAL MAN'S STANDPOINT.

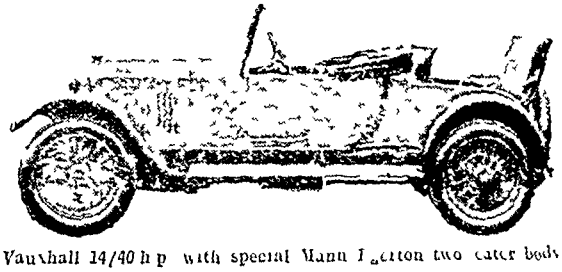


BY

H MASSAC BUIST

The eighteenth yearly International Motor Car Show, which closes at Olympia, Kensington, at 10 o'clock on Saturday night, must be pronounced by far the greatest of the series, and the one which has made the most striking appeal to the medical motorist It contains even promise of better things to come Thus the very largely used system of grease-gun lubrication for the chassis, which revolutionizes the vexed problem of proper yet easy maintenance, may in a year or so be further simplified by the use of a new material, the Belflex-Hobson fabric spring-shackle engine and torque arm mountings This means that spring-shackles—one of the most frequently neglected parts of a vehicle from the point of view of lubricant, and a great source of squeaking—can be replaced by what is really a development and adaptation of the principle of the Hardy universal fabric joint, which is a cheap and successful substitute for one of the most expensive and complex, as well as the hardest worked, pieces of a car mechanism—namely, the universal joints at either end of the propeller shaft Belflex material comes from America, but is as yet no further advanced in general application there than it is here, though we shall certainly hear more of it in twelve months' time By the use of this material for such parts as shackles, and so on, it would not be necessary to supply them with lubricant

Coachwork

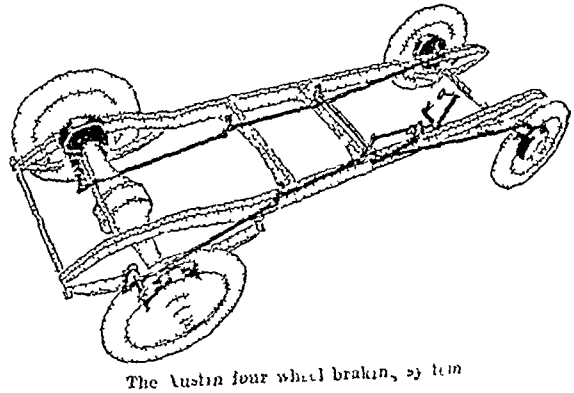


De Dion Bouton, as stated last week, introduces this year, on a 12/28-h p four wheel brakes chassis, an "occasional

De Dion Bouton 12/28 h p with London built coupe cabriolet body

four" coupe type of good interior illumination and notably easy access The seat beside the driver is tilted forward when it is desired to enter, or to leave, the rear collapsible seats, which are accommodated very neatly when not in service Regarding cars standardized with complete equipment in the form of four- or five-seat open-work bodies, it is to be noted that a great number are provided now with rear windscreens, also that most of these devices enable the screen to be thrust sideways to give convenient entrance to the car when the screen is in use The Humber curtaining scheme on the all-weather type of body is one of the neatest hitherto designed—alike from the points of view of erecting it in a moment and of stowing it quite out of sight and most conveniently when not in use It can be stated that the all-weather curtaining schemes on most cars really afford adequate protection, together with the provision of good visibility for safe driving Further, convenient driving is assisted greatly by the fact that this year a very large number of makers, particularly of cars of limited chassis space, nevertheless continue to provide independently adjustable front seats to accommodate the particular requirements as to leg length, and so forth, of the individual occupants, yet many of these devices are of types that do not develop rattle with wear Quite extraordinary things are being done in the matter of coachwork at really cheap prices—for instance, the new four-seat open touring all-weather British-built bodies on the Citroen chassis

The most notable entirely new contribution from abroad to the problem of the small scale car is provided by Citroen on a 11 4-h p four-cylinder engined chassis This maker has arrived at the conclusion that steel, instead of wood, should be used for the bodies His new car is a four seat saloon body on a 11 4-h p 1,453 c cm four-cylinder engined chassis, one advantage of the steel body is that it gives proportionately a greater range of vision to driver and to passengers because the posts are the smallest ever devised Other gains of this construction are the lightness without



Vauxhall 14/40 h p with special Mann Egerton two seater body

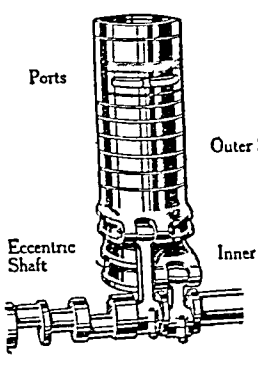
sacrifice of strength, freedom from distortion and rattle, and the quality of being fireproof This four-seater, as exhibited, is sold retail at £325 The Citroen works are now producing 300 cars a day, which is a record for the European industry and an explanation of the low scale prices ruling this year As mentioned in these columns a month ago, Citroen was the first big scale maker to standardize balloon tyres on all his models, to the great improvement of their riding qualities

This system is in striking contrast with the flexible, non-rigid fabric Weymann method of construction, which could have been evolved to solve the problems of squeak and distortion only through applying aircraft engineering practice This type of covered body is listed as an alternative by a number of chassis builders Its use is for the permanently covered type of coachwork, and it is available in that form even on so small a machine as the 8-h p two-cylinder air-cooled engined Rover The Weymann body is manufactured under licence by Singer among many others Singer uses detachable pneumatic upholstery Wolseley, Lancia, and Singer show new-style fabric body materials that are really British in conception, whereas the original fabric body patterns were not

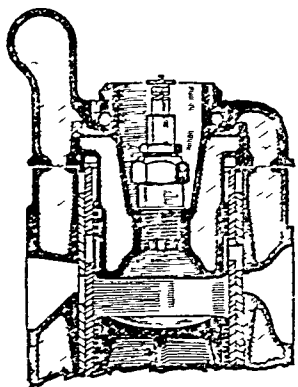
Of bodies built to special design there is a clever provision of what one might style a "semi-coupe" in the Mann Egerton blue granite two-seater, with commodious and comfortable dickey seat, provided on a 14/40-h p developed four-speed right-hand controlled Vauxhall chassis, the trimmings being blue antique leather The body panels are done in aluminium, and are equipped with quick operating hood fittings, together with all-weather side curtains that open and close with the doors, the price of the car complete is £650 This type of body can be

The Austin four wheel braking system

built broader at an inclusive price of £200 The S F. Edge patented "open-closed" compact light-weight body that is usable either as a two-three seat open touring car or as a coupe type is clever, the six cylinder chassis being available now with longer wheel-base, also with a four wheel braking system The Austin four wheel braking system, illustrated above, is so arranged that the



pedal action applies braking action to all four wheels in synchronism, with suitable compensating mechanism, provision being made for quick and easy adjustment A rod connects the pedal with the brake-operating cross member, the actual connexion to each wheel being by a cable



HINTS TO USERS OF "BALLOON" TYRES

The increasing use of shock-absorbers combined with the employment of low pressure tyres, serves as an intermediate makeshift measure in dealing with the problems of suspension It may be stated broadly that a happy compromise is being reached, though in connexion with the low pressure tyre it is to be observed that Minerva and Willys-Knight use a semi balloon type, as do some others On the large heavier car constructions the semi balloon tyre does not tend to drag at the corners Regarding this development Lieut Colonel Sealy Clarke, President of the Society of Motor Manufacturers and Traders, uttered a useful warning in the *Motor* concerning the manner of obtaining the best results from low pressure pneumatics This type needs to be watched more carefully to see that it is at the correct pressure than does an ordinary tyre, otherwise undue cost for damaged tubes and wall wear will follow For instance, with a normal tyre run at a pressure of 65 lb to the square inch, it matters relatively little that it is being run at 60 or even 55 lb whereas the loss of 5 lb in a balloon tyre inflated at 25 lb per square inch will alter the character of its riding altogether as also the strains imposed on it, as well as its behaviour at corners and so on It is not possible to forecast at present what wearing life can be expected of balloon tyres because the only statistics available are those by experts Data are needed concerning what happens in the hands of the inexpert—otherwise the general public There is no reason to anticipate a shorter wearing life than with normal section tyres, provided attention is given to correct inflation In any case the use of the balloon tyres in cars of poor suspension or with relatively weak springs, should result in economy in shackles, wear, and so forth But all tyre companies rightly stress the need continually to make sure that one is not driving with such pneumatics underinflated The consensus of expert opinion at the moment is that any under inflation beyond 10 per cent spells actual danger The Goodyear company states that balloon tyres are for comfort not 'stunting", therefore nothing could be more foolish than to drive over the edge of a curb or similar obstruction with a car shod with low pressure tyres because the shock to the thin walls may cause irreparable damage

DOUBLE SLEEVE VALVE ENGINE DEVELOPMENTS

It is more than half a generation since an American, who knew nothing whatever about engineering, Mr Charles Y Knight, discovered how to make a liquid fuel internal combustion engine which would function silently because instead of having poppet valves he inserted two sliding sleeves with slots in them, in the cylinders The principle was tried in America but nobody could make a success of it The invention was then brought to Sir Edward Manville chairman of the Daimler Company in this country and Mr Percy Martin experimented with it At first engineers said it was impossible because the sleeves could not be lubricated But a natural law, as distinct from man's ingenuity, looked after that automatically the sleeves lubricated themselves by capillary attraction In the issue it was found that this was —and it remains—the only type of motor car engine which works best in the natural condition of a gas engine—namely, when the sleeves are dirty, for example, gas-tight with lubricant As soon as the type was made successfully the Daimler Company pioneered it introduction to the public by putting it to a week's test on the bench, and the challenge issued by the company at the conclusion of that successful test till remains to be taken up Silent-acting valve gear on motor cars in general dates from, and is a consequence of, the introduction of that engine, which has been taken up under licence by Mercedes in Germany by Panhard in France, by Minerva in Belgium, and by Willys-Knight in America Today among other firms exploiting the type, is Voisin, the aeroplane builder, who now makes cars The licencees pool their improvements For a long time the sleeves were made of cast iron Much of the improvement in the performance of these engines is due to the more recent use of steel sleeves In the beginning too the cylinders were cast in pairs, now most of the licencees make monobloc engines even as are the poppet valve types with the result that much better rigidity is gained It was in connexion with this engine that Professor F W Lanchester evolved his harmonic balancing gear for dealing with secondary inertia forces in the crank case Even the American version of this engine, made by Willys-Knight has been improved greatly in performance this year by altering the position of the valve ports and by applying this Lanchester harmonic balancing gear The American types have four cylinders only, and therefore need it even more than do the six-cylinder types which are the more generally favoured system in Europe These engine are to-day standardized with much higher compressions They are supplied to the King's four new cars that replace the machines with the same sort of engine which his Majesty has had in use for thirteen and fourteen years respectively

The Daimler pocketless combustion chamber

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER

(Continued from page 772)

THE sittings of the Royal Commission on Lunacy and Mental Disorder were resumed on October 21st the Right Hon HUGH P MACMILLAN K C, presiding

Sir CLAUDE SCHUSTER permanent secretary to the Lord Chancellor desired to amplify an answer which he gave at the previous hearing when he said that he hoped a lunatic in confinement did not possess or would not be given the right to demand a public inquiry as to whether he had recovered He explained that he held this opinion because (1) lunacy was a disease whose cure or alleviation was a gradual process and the determination whether the patient had reached a point at which he might properly be released was a matter peculiarly unsuited for public inquiry (2) the function of those who had to determine whether the patient was to be released or further detained was not to investigate any charge against a patient as if he were an alleged criminal and it would be very undesirable that the local authority or the person in charge of the asylum should be forced into an office analogous to that of prosecutor and (3) a very large proportion of lunatics considered that they were wrongfully detained and every one of these people would have the right to demand an inquiry a lunatic's condition was unsuitable for public discussion and the details would be often unpleasant and sometimes humiliating for the patient, and detrimental to his interests

Evidence of the Ministry of Health

Mr L G BROCK, Assistant Secretary of the Ministry of Health described how certain powers and duties with regard to insane persons had been transferred from the Local Government

Board and the Home Office to the Ministry of Health These powers and duties might be grouped broadly under four heads (1) the limited powers of the Ministry with regard to the individual lunatic (the Minister could not order discharge, but he could institute inquiries on complaint), (2) approval of plans of local authorities and visiting committees for the purchase of land and erection of buildings, (3) certain powers relating to the Board of Control, concerning the Ministry's voice in some appointments to and by that Board, and responsibility for the Board's estimates in Parliament (the Ministry had no power to give directions to the Board for any specific administrative act, but as a matter of practice the Board invariably met the Minister's wishes), (4) its power to direct the Attorney General to prosecute any person alleged to have committed a misdemeanour under the Act

In reply to the chair, Mr Brock described the daily work of the division of the Ministry which dealt with lunacy administration All letters from patients were carefully read by a responsible officer, and, whenever necessary, the Board of Control was consulted regarding the latest medical report on the condition of the patient whose case was the subject of a letter This did not apply, of course, to a number of chronic patients, who wrote regularly, for the mental condition of these people was well known to the department, and there were other cases in which the letters bore on the face of them unmistakable evidence of insanity, a frequent complaint from patients was that they were being "poisoned by wireless", one patient wrote that he was "having communism injected into him by psycho analysis" Apart from these and similar exceptions, however, the most careful attention was given to every letter, and the Board of Control, if it had no recent report on the case available, obtained a special report, at the Ministry's request, on any case in which there was an allegation of wrongful detention or ill treatment When there was still room for doubt the Ministry asked that the Commissioners at their next visitation should pay special attention to the patient It a case presented medical as distinct from psychiatric issues which called for investigation, a medical officer of the Ministry was sent to report upon it In only one case of recent years had it been found necessary to resort to an independent inquiry

Mr Brock went on to say that the evidence available to the Ministry did not suggest that persons were improperly certified or detained longer than the medical superintendent believed to be necessary, nor had any allegations of ill treatment been fully substantiated At the same time it was clear that there were a number of patients in mental hospitals who, though in no sense sane, could be discharged without danger to themselves or the community if their relatives were willing and able to look after them The exact point at which a person suffering from mental disorder was sufficiently recovered to justify discharge was necessarily a matter of opinion, and some superintendents, mindful of the risks they incurred by recommending discharge prematurely, were more cautious than others It was also remarkable that in many instances where the relatives were convinced that the case was one of improper detention the medical report indicated a definitely bad prognosis The explanation might be that in certain forms of insanity which were slow in development there were periods of quiescence, and as the relatives were only allowed to see the patient on good days, they formed an incorrect impression of his mental condition Other cases developed acute symptoms at an early stage, and, though the prognosis was hopeful, the relatives, having seen the patient violent or raving before removal to the asylum, had no doubt as to his insanity and not much hope of his recovery

SIR HUMPHRY ROLLESTON asked what were the advantages of having the Board of Control as a separate authority, instead of an ordinary department of the Ministry MR BROCK said that he would prefer not to express any opinion on such a large matter of policy At present the relations between the medical Commissioners of the Board and the medical officers of the Ministry depended upon mutual courtesy and a regard for administrative convenience

Administration of the Poor Law in relation to Lunatics

MR H W S FRANCIS, assistant secretary of the Poor Law Division of the Ministry of Health, gave evidence as to the functions of the Ministry as the successor of the Local Government Board in the administration of the Poor Law His department kept in close touch with the administration of the local Poor Law authorities through a body of general inspectors, and medical officers, and every Poor Law institution was visited at least once a year The general inspectors had a statutory power of holding inquiries upon oath During the last five years such formal inquiries had been held in two cases in which persons of unsound mind were concerned In one case a representative of the Board of Control sat as assessor There had been other cases in which, after considering the report of the inquiry made by the Poor Law authority concerned and the action taken, it had seemed unnecessary that a departmental inquiry should be held The witness went on to give some statistics On January 1st there were 1,372,098 persons in receipt of Poor Law relief, of whom 125,972 were receiving relief on account of lunacy or other mental infirmity (93,733 in lunatic asylums, where their care was mainly the responsibility of the asylum authorities and the Board of Control, 4,707 in receipt of outdoor relief, and 27,432 in Poor Law institutions or institutions, other than asylums, maintained wholly or partly out of the poor rate) Of these 27,432 persons, 8,763 were inmates of Poor Law institutions provided solely for mental cases, and almost all the remainder were inmates of the sick or other wards of ordinary Poor Law institutions

Duties of Relieving Officer under the Lunacy Acts

The next witness was MR E J LIDBETTER, President of the National Association of Relieving Officers, who, on behalf of the body he represented, made a number of recommendations The first of these was that there should be no difference in the process of certification between the pauper and the non pauper case Juveniles—by which he meant persons under 16 who were imbeciles or idiots—should not, except in very rare cases, be certified as insane, nor should cases of senile dementia The provisions of the Mental Deficiency Act should be amended to enable juvenile pauper cases to be dealt with under its provisions He thought also that the Board of Control or some other authority or commission should be endowed with powers to determine under proper safeguards ambiguities in the statutes and points of law involved, and he described to the Commission some of the difficulties which relieving officers encountered—difficulties in many cases only to be got over by evasions of the law in the interests of the patient and the public

The chief recommendation of the witness, however, was that the workhouse should no longer be regarded as a place of safety for alleged lunatics, but Asylums Committees should be required to provide sufficient reception houses in all urban areas In such centres there would be sufficient cases to justify and require a rota of justices holding a daily session The preliminary period of detention need not then be as long as three days Such daily centres would be more formal and would conduct the investigation of cases in a more judicial atmosphere than was possible in the wards of a workhouse There would be a resident medical officer available at these reception houses for the purpose both of observation and treatment The reception house should also serve the purpose of a clinic for the provision, under proper circumstances, of advice and treatment to out patients On a recommendation for the discharge of a patient from an institution for lunatics the staff of the reception house would inquire into and report upon the conditions into which it was proposed to release the patient, and, on his release, would make some provision for after care

The CHAIRMAN said that the Commission was anxious to recommend the best provision possible, but he rather feared that the expense of such a scheme might be an objection He quite saw the importance of the proposal, but it was necessary to cut the coat to suit the cloth

MR LIDBETTER admitted that some of the branches of his own organization were not in favour of the scheme owing to its probable expenditure But he thought that the expenditure might not be as great as was anticipated, especially in view of the workhouse accommodation, in London at all events, now available for other than ordinary use

Nova et Vetera.

THE MEDICAL KNOWLEDGE OF CHARLES DICKENS

MRS GARGERY'S ILLNESS

MANY will recall passages from the works of Dickens in which he displays a familiarity with matters pertaining to medicine When his characters suffer, through illness or accident, he describes their symptoms with great minuteness, and in the case to which I wish particularly to refer he also shows great accuracy

Those who have read *Great Expectations* will remember the dastardly attack on Mrs Joe Gargery, the wife of the village blacksmith, who was struck on the back of the head and on the spine by an unknown hand The incident is described at the end of Chapter 15 and in Chapter 16

The immediate symptoms from which Mrs Gargery suffered, and more especially those which were evident later, are of interest in revealing the extent of medical knowledge possessed by Dickens Further, this keen observer, in his description of the later symptoms, has anticipated by

some years, as shall be shown, the findings of our great neurologists.

Let us first, then, consider the story of the assault and the description of the symptoms which followed, as Dickens has it:

"I became aware of my sister lying without sensation or motion on the bare boards where she had been struck down by a tremendous blow on the back of the head dealt by some unknown hand when her face was turned towards the fire.

She had been struck with something heavy on the head and had fallen at the blows were dealt something had been thrown down at her with considerable violence as she lay on her face. And on the ground beside her was a convicts leg iron which had been filed asunder."

Such an instrument would give a depressed fracture and the "tremendous blow" would cause widespread damage to the posterior portion of the brain. The next symptoms to be mentioned occur after some lapse of time:

"Long after these constitutional powers (the constables and Bow Street men) had dispersed my sister lay very ill in bed. Her sight was disturbed so that she saw objects multiplied and grasped at visionary tea-cups and wine-glasses instead of the realities. Her hearing was also greatly impaired, her memory also, and her speech was unintelligible. When at last she came round so far as to be helped downstairs it was still necessary to keep my slate always by her that she might indicate in writing what she could not indicate in speech. As she was (very bad handwriting apart) a more than indifferent speller, and as Joe was a more than indifferent reader, extraordinary complications arose between them which I was always called in to solve. The administration of matter for medicine, the substitution of Tea for Joe, and the baker for bacon, were among the mildest of my own mistakes. However, her temper was greatly improved, and I was present at the tedious unsteadiness of the action of all her limbs soon became a part of her regular state, and afterwards, at intervals of two or three months, she would put her hands to her head, and would then remain for about a week at a time in some gloomy aberration of mind."

It may have been about a month after my sister's appearance in the kitchen when Biddy came to me. Biddy's first triumph in her new office [that of assistant on Mrs. Gargery] was to solve a difficulty that had completely vanquished me. This was: Again and again and again my slate had traced upon the slate a character that looked like a curious T, and then with the utmost eagerness had called our attention to it as something she particularly wanted. I had in vain tried everything producible that began with a T, from tar to toast, and had even got into my head that the sign looked like a hammer, and on mentally calling that word in my sister's ear she had begun to hammer on the table and had expressed a qualified assent. Thereupon I had brought in all our hammers, one after another, but without avail. Then it occurred to me, as a last resource, to draw the shape, being much the same, but she shook her head.

When my sister found that Biddy was very quick to understand her, this mysterious sign reappeared on the slate. But it looked thoughtfully at it, looked toughtfully at Joe (who was always represented on the slate by his initials), and ran into the forge. Why, of course! cried Biddy with an exultant face. Don't you see? It's him! Orlick, without a doubt! She had lost his name, and could only signify him by his hammer. I confess that I expected my sister to denounce him. She manifested the greatest anxiety to be on good terms with him, was evidently much pleased by his being at length produced, and protested that she would have him given something to drink."

Later, towards the end of Chapter 18, we have another glimpse of our patient:

"Infinite pains were taken by Biddy to convey to my sister some idea of what had happened [that is, that Pip had now great expectations]. To the best of my belief, those efforts entirely failed. She laughed and nodded her head a great many times, and even repeated after Biddy the words 'Pip' and 'Property.' But I doubt if they had more meaning in them than an election cry, and I cannot suggest a darker picture of her state of mind."

Again we see the household at supper, with Biddy sitting "holding my sister's plate," and towards the end of Chapter 19 we find Mrs. Gargery "laughing and nodding and shaking in her usual chair."

Some time afterwards—it would be difficult to state exactly how long—Pip has news of the death of his sister. After the funeral he has a talk with Biddy:

"'I have not heard the particulars of my sister's death, Biddy,' I say. She replies: 'They are very slight, poor thing. She had been in one of her bad states—though they had got better of late rather than worse—for four days, when she came out of it in the evening, quite early tea-time, and said quite plainly, Joe.' She made signs to me that she wanted him to sit down close to her, and so she presently said, 'Joe,' again, and once, 'Pip.' And so she never lifted her head up any more."

Such, then, is the account of Mrs. Gargery's illness, caused by a blow from a blunt heavy instrument "on the back of the head," described again as "on the head and spine", let us examine in detail the symptoms which she showed, and see how far they coincide with our present knowledge of cerebral injuries. The first symptoms to be mentioned are those following the blow, that is, concussion:

"I became aware of a confusing impression that I had been through this before, that I had seen this before, that I had been lying in this place before, and had been moved from this place, and had been carried past this window, and had been spoken to by these voices, and had seen this light in the ceiling above me, from this very spot. Then, all in a moment, my head became very painful, and very full, and very empty, and I knew nothing."

Next we have the period of unconsciousness, followed by the return of consciousness:

"I began to see things and people about me. By degrees, I could hear what was said, and could speak consecutively. After an interval, I knew that I was lying in bed, and that Biddy was sitting by me, and I put out my hand and touched her arm. She was overjoyed to see me conscious, and controlled herself and me, lest we should disturb the rest of the house. She said that we were quiet and must be very thankful. She said no more at that time, and I closed my eyes again."

Then we have the period of confusion:

"Long after these constitutional powers (the constables and Bow Street men) had dispersed, my sister lay very ill in bed. Her sight was disturbed so that she saw objects multiplied and grasped at visionary tea-cups and wine-glasses instead of the realities. Her hearing was also greatly impaired, her memory also, and her speech was unintelligible. When at last she came round so far as to be helped downstairs it was still necessary to keep my slate always by her that she might indicate in writing what she could not indicate in speech. As she was (very bad handwriting apart) a more than indifferent speller, and as Joe was a more than indifferent reader, extraordinary complications arose between them which I was always called in to solve. The administration of matter for medicine, the substitution of Tea for Joe, and the baker for bacon, were among the mildest of my own mistakes. However, her temper was greatly improved, and I was present at the tedious unsteadiness of the action of all her limbs soon became a part of her regular state, and afterwards, at intervals of two or three months, she would put her hands to her head, and would then remain for about a week at a time in some gloomy aberration of mind."

It may have been about a month after my sister's appearance in the kitchen when Biddy came to me. Biddy's first triumph in her new office [that of assistant on Mrs. Gargery] was to solve a difficulty that had completely vanquished me. This was: Again and again and again my slate had traced upon the slate a character that looked like a curious T, and then with the utmost eagerness had called our attention to it as something she particularly wanted. I had in vain tried everything producible that began with a T, from tar to toast, and had even got into my head that the sign looked like a hammer, and on mentally calling that word in my sister's ear she had begun to hammer on the table, and had expressed a qualified assent. Thereupon I had brought in all our hammers, one after another, but without avail. Then it occurred to me, as a last resource, to draw the shape, being much the same, but she shook her head.

When my sister found that Biddy was very quick to understand her, this mysterious sign reappeared on the slate. But it looked thoughtfully at it, looked toughtfully at Joe (who was always represented on the slate by his initials), and ran into the forge. Why, of course! cried Biddy with an exultant face. Don't you see? It's him! Orlick, without a doubt! She had lost his name, and could only signify him by his hammer.

I confess that I expected my sister to denounce him. She manifested the greatest anxiety to be on good terms with him, was evidently much pleased by his being at length produced, and protested that she would have him given something to drink.

Later, towards the end of Chapter 18, we have another glimpse of our patient:

"Infinite pains were taken by Biddy to convey to my sister some idea of what had happened [that is, that Pip had now great expectations]. To the best of my belief, those efforts entirely failed. She laughed and nodded her head a great many times, and even repeated after Biddy the words 'Pip' and 'Property.' But I doubt if they had more meaning in them than an election cry, and I cannot suggest a darker picture of her state of mind."

Again we see the household at supper, with Biddy sitting "holding my sister's plate," and towards the end of Chapter 19 we find Mrs. Gargery "laughing and nodding and shaking in her usual chair."

Some time afterwards—it would be difficult to state exactly how long—Pip has news of the death of his sister. After the funeral he has a talk with Biddy:

"'I have not heard the particulars of my sister's death, Biddy,' I say. She replies: 'They are very slight, poor thing. She had been in one of her bad states—though they had got better of late rather than worse—for four days, when she came out of it in the evening, quite early tea-time, and said quite plainly, Joe.' She made signs to me that she wanted him to sit down close to her, and so she presently said, 'Joe,' again, and once, 'Pip.' And so she never lifted her head up any more."

Such, then, is the account of Mrs. Gargery's illness, caused by a blow from a blunt heavy instrument "on the back of the head," described again as "on the head and spine", let us examine in detail the symptoms which she showed, and see how far they coincide with our present knowledge of cerebral injuries. The first symptoms to be mentioned are those following the blow, that is, concussion:

"I became aware of a confusing impression that I had been through this before, that I had seen this before, that I had been lying in this place before, and had been moved from this place, and had been carried past this window, and had been spoken to by these voices, and had seen this light in the ceiling above me, from this very spot. Then, all in a moment, my head became very painful, and very full, and very empty, and I knew nothing."

Next we have the period of unconsciousness, followed by the return of consciousness:

"I began to see things and people about me. By degrees, I could hear what was said, and could speak consecutively. After an interval, I knew that I was lying in bed, and that Biddy was sitting by me, and I put out my hand and touched her arm. She was overjoyed to see me conscious, and controlled herself and me, lest we should disturb the rest of the house. She said that we were quiet and must be very thankful. She said no more at that time, and I closed my eyes again."

Then we have the period of confusion:

remain for about a week at a time in some gloomy aberration of mind" Mrs Gargery before her injury is described as being a person of great irritability of temper, easily provoked, and subject to fits of most violent passion "She's been on the Rampage, this last spell, about five minutes," said Joe, while Pip writes, "She concluded by throwing me—I often served her as a connubial missile—at Joe", and later, "She pounced on Joe, and, taking him by the two whiskers, knocked his head for a little while against the wall behind him"

In a person of so violent a temper cerebral concussion would most likely be followed by symptoms of concussion neurosis, and also katatonic stupor, as mentioned by Purves Stewart, and, indeed, to such conditions does the above description of the "bad state" point The tremors which are often a marked feature of these traumatic neuroses are also mentioned to complete the clinical picture—"A tremulous uncertainty of the action of all her limbs soon became a part of her regular state", while the glimpse of Biddy holding the patient's plate for her at supper reveals this "tremulous uncertainty" That the patient's temper should have become improved as a result of the concussion is, however, an exception to the rule

In the light of our modern knowledge, does not this account of Mrs Joe Gargery's illness, the result of a widespread lesion of the posterior aspect of the brain, reveal Dickens to be a most wonderfully minute and accurate clinical observer? He would not realize the significance of his observations from a scientific medical standpoint, but the fact remains that he has described nothing that is not in keeping with present neurological knowledge His information could not have been obtained from medical friends or from medical literature, as will be shown, he must have gained it purely by his own observation

Great Expectations was written in 1861 What was the existing knowledge of the functions of the cerebral hemispheres at this time? It was known to Galen that the occurrence of paralysis on one side of the body was the result of lesions in the brain of the opposite side The theory that the functions of the brain can be localized in the cerebral cortex was introduced in somewhat fantastic form by Franz Joseph Gall as organology or cranioscopy, and by his pupil Spurzheim as phrenology, their joint researches appeared as a four-volume treatise with atlas (1810-19) Flourens in 1822-24 made his observations on the effects of removing the cerebrum and cerebellum in pigeons, showing the absolute maintenance of reflexes with loss of cerebration and volition in the former case and disturbance of equilibrium in the latter In 1828 he located the existence of true cerebellar and labyrinthine vertigo (Garrison)

In the same year as *Great Expectations* appeared Broca, confirming older statements by Dax and by Bouillaud (1825), maintained that aphasia, when it occurred in right-handed people, was always associated with a lesion of the third frontal convolution of the left hemisphere In 1836 Richard Bright had described localized epileptiform spasms from definite cerebral lesions, to be confirmed later (1864) by Hughlings Jackson Such, then, was the knowledge existing in 1861 upon the subject of localization of function of the brain It was some years afterwards (1865-72) that Meynert made his investigations on the anatomy and physiology of the brain He pointed out, on anatomical grounds, that the posterior portions of the hemispheres were probably more nearly connected with sensation, and the anterior with the power of movement Sir David Ferrier (1872-76) described the localization of sensory functions in the cortex, and in 1874 Wernicke described sensory aphasia, including alexia and agraphia In 1876 Flechsig mapped out the special motor and sensory, as well as the "silent," or inexcitable, areas in the cerebral cortex (Garrison)

Thus it will be seen that Dickens, in his account of Mrs Joe Gargery's illness, must have described a case which he had actually met with in life and observed himself The extreme accuracy of the description shows him to have been possessed of powers of medical observation far in advance of the clinicians of his day

CHARLES G STRACHAN, M B Durh, M R C I Edin

Edinburgh

Scotland.

VITAL STATISTICS OF SCOTLAND

THE Scottish Registrar-General's Report for the year 1923 has now been issued[1] It contains the usual detailed and well arranged information as to births, marriages, and deaths in the country as a whole, in the largest cities and towns, and in the public health districts of the counties Some of the main facts relating to the whole of Scotland are as follows

The population at the middle of the year is estimated at 4,901,100 Owing to large emigration, there is a reduction of 3,356 as compared with the previous year, though the total is 18,603 more than in the census year 1921 The births were 111,902, or at the rate of 22 83 per 1,000 of population, this being the lowest rate since registration began in 1855, excepting the three years 1917, 1918, and 1919 Expressed per 1,000 of women of the child bearing age, 15 to 45 (married and unmarried), the birth rate was 93 6, or 2 6 less than in the previous year The illegitimate births were only 6 68 per cent of the total births, this also being the lowest recorded Illegitimacy varied remarkably as between different parts of Scotland, it being [illegible] counties (including the burghs) of Wigtown [illegible] in the south west, and also in the north eastern counties—Aberdeen and those on the Moray Firth In the industrial region—Lanark, Renfrew, Dumbarton, etc—it was very low The marriage rate for Scotland was 7 19 per 1,000, being rather higher than in 1922, but lower than in the preceding five and ten years

Infant Mortality—The infant mortality rate was only 78 6 per 1,000 births, this being very decidedly the lowest on record, the previous minimum having been 90 3 in 1921 The year's rate is 18 1 per cent less than the mean of the preceding five years, and 24 7 per cent less than that of the preceding ten years—a notable and gratifying reduction In the counties, including the burghs, the rate ranged from 36 in Shetland to 101 in Banff

Cancer—Among the causes of death more than usually prevalent was cancer Its deaths were 6,376, or 790 in excess of a ten yearly mean Stated per 100,000 of population the rate was 130 Fifty years ago, in 1873, deaths from phthisis outnumbered those from cancer by 6,749, or nearly 440 per cent, but cancer deaths now outnumber phthisis by 2 380, or 60 per cent The cancer death rate in males in 1923 was 118 per 100,000, and in females 142, the former being 7 and the latter 4 more than in the previous year Of the total 6,376 deaths from malignant disease, 4,377 were ascribed to carcinoma, 276 to sarcoma, and 1,723 to other or unspecified forms

Tuberculosis—The death rate from all forms of tuberculosis in 1923 was 118 per 100,000, and is the third consecutive annual rate of less than 120, and the fifth less than 140 The deaths in 1923 were 5,790, in 1870 (in a much smaller population) they were 13,027, or 404 per 100,000 Of the total 5,790 tuberculosis deaths in 1923, there were attributed to the respiratory system 3,996, to tuberculous meningitis 664, to tuberculosis of the intestines and peritoneum 521, of the spine 97, of the joints 53, whilst 459 others included 138 acute and 171 chronic disseminated tuberculosis The skin accounted for 12, the bones (except spine) 23, the lymphatic glands other than abdominal 20, and the genito urinary system 55

Principal Causes of Death—A table of the relative frequency of causes of death in 1923 states every cause which produced more than 1 per cent of the total Heart disease accounted for 10 90 per cent, malignant tumours 10 08, apoplexy 9 13, pneumonia 7 39, diseases of early infancy and malformations 6 72, tuberculosis of the respiratory system 6 31, bronchitis 5 65, violence 3 90, nephritis, acute and chronic, 2 84, measles 1 77, whooping cough 1 56, diseases of the respiratory system other than tuberculosis, bronchitis, and pneumonia, 1 33, diseases of arteries 1 27, diarrhœa and enteritis (under 2 years) 1 25, and tuberculous meningitis 1 05 This list includes 71 2 per cent of the total deaths In 1922 a severe epidemic of influenza caused 5 08 per cent of the total deaths, but in 1923 the percentage was only 0 84 Deaths from pneumonia and bronchitis also contributed a smaller percentage of the total than in 1922, and thus helped to raise the relative percentages of deaths from other causes

Vaccination—The annual report on this subject relates to 1922, not 1923 Of 115,085 children born, 8,168 died before reaching the statutory vaccination age of 6 months Of the remainder, 62 10 per cent were certified as successfully

[1] H M Stationery Office, 120, George Street Edinburgh, and at H M Stationery Offices in England and Wales (8vo, pp cxxix + 152, 10s 6d. net 10s. 10d post free)

[illegible] to be insusceptible owing to previous [illegible] 983, or 0 92 per cent, were returned as [illegible] r reasons, and 36 98 per cent were reported unvaccinated, of whom 33,224 had been the subject of declaration of conscientious objection. The percentage successfully vaccinated is 0 36 less than in 1921 and is also less than in 1920, but is greater than among children registered in each of the years 1913 to 1919 It will be noted that the percentage vaccinated, being over 62, is much higher than in England, which is under 40 Previous to the Act of 1907 more than 91 per cent of the surviving births were vaccinated

Royal Medical Society of Edinburgh

The 188th session of the Royal Medical Society was inaugurated on October 17th by an address from Sir Ronald Ross, K C B, K C M G, F R S, Dr A B Williamson, senior president of the society, presided over a large attendance The lecturer took as his subject "Thoughts on medical discovery," and said that a very brief study of civilization showed that new discoveries constituted a rare phenomenon which tended to be localized both in time and place The Graeco Roman period of discovery had lasted about nine centuries, and thereafter a long negative period ensued for about eleven or twelve centuries, during which hardly any advance had been made Then suddenly, in the fourteenth and fifteenth centuries, a period of rebirth had begun almost simultaneously in every line, including art, literature, science, exploration, and philosophy A theory had been advanced by Sir Flinders Petrie that the cause of the periodic augmentations of intellectual vigour lay in the admixture of races from time to time by permeation or conquest Some centuries after admixture with a foreign race the vigour of a people began to increase, and arts and sciences were discovered or rediscovered, then gradually came regression and decay until subsequent infusions or conquests occurred It was unlikely that at any given time all the world's nations should be in the same state of development It might be said that to-day India and China were in the slack state as compared with Europe, and that Europe was approaching the slack state as compared with America The lecturer added that new discoveries in medical science were scanty in comparison with the large numbers engaged in this pursuit, but the same thing applied to all other departments of life Medical discovery was to human beings the most important of all kinds of discovery, and the amount of public attention given to it was disproportionately small The total amount provided for research every year in this country was probably only £180,000, which was equivalent to 1d per annum for each person in Great Britain For this penny everyone hoped to have his life prolonged! Eighty years ago the average expectation of life in London was under forty years, but it had been prolonged until it was now sixty years, and he saw no reason why the average expectation of life should not be prolonged to the seventy years of the Psalmist He had often wondered what would be the length of life if an individual were kept entirely free from pathogenic organisms and deleterious foods and drinks It was not known why elephants, parrots, and tortoises should live for more than a century while horses and dogs died before twenty years of age, this, too, might be a subject for research The nation had to pay millions of pounds for its protection from foot-and-mouth disease largely owing to the fact that it refused to pay small sums for the investigation of the disease Doctors and men of science might congratulate themselves personally on the fact that almost all the discoveries that had been made were made by them without help from anyone else, at the expense of the investigators themselves, but the world would be well advised to spend much more than it was now doing on investigating how diseases of all kinds might be fought

Regius Chair of Surgery in Glasgow University

Professor Archibald Young, M D, the new Regius Professor of Surgery in Glasgow, in his inaugural lecture on October 13th, dealt with the history and progress of surgery in Glasgow, with special reference to his predecessors in office Since the Regius Chair was founded, in 1815, there had been five previous occupants, all distinguished, each had helped to establish the high credit of surgery and of surgical teaching in Glasgow and in Scotland He gave a brief account of their achievements, referring more particularly to the epoch making work of Lister and Macewen He pointed out the great traditions to which he and all medical students in Glasgow University were heirs, and which it would be their duty and privilege to honour and maintain Professor Young concluded by referring to one great need of the Glasgow School of Surgery—a properly equipped surgical museum—and made a strong appeal for help in the founding and equipping of such a collection

Sir Malcolm Watson's Lectures in Glasgow

A series of lectures was given during last week in the University of Glasgow by Sir Malcolm Watson, M D, LL D, on anti-mosquito work in the tropics Principal Sir Donald MacAlister presided over large and interested audiences The lecturer described the method of examining malarial blood for the parasite, and explained in detail the various forms of parasite seen in the disease and their mode of growth He reviewed the different ways in which the parasite, having established itself in the human body, might accomplish the destruction of its host He showed how in many parts of the tropical world among races which had been long infected by the disease there had developed a partial immunity The parasite there infected the young children at an early age, if not too heavily infected they gradually became immune, and parasites could not be discovered in their blood In his second lecture Sir Malcolm traced the history of the malarial parasite in its passage from man through the mosquito back to man, giving in detail a review of the work of Sir Ronald Ross and his discovery that the sexual life history of the parasite was passed in the anopheles group of mosquitos, which could transmit the disease Many slides were shown in illustration, lent by Sir Ronald Ross, some being photographs of the original dissections made by him in Calcutta in 1898 In the third lecture Sir Malcolm Watson referred to the discovery that mosquitos not only carried malaria but also yellow fever, as was demonstrated by a commission of American workers in Cuba in 1900, during the Spanish-American war, when this fever was specially severe A different type of mosquito, the *Stegomyia fasciata*, was found to transmit this disease An active campaign against the mosquito during the following year cleared this disease out of a city from which it had not been absent for over two centuries The lecturer then described the wonderful achievements in preventive medicine of the American in the Panama Canal zone From 1904 to 1906 sanitary work was carried on which resulted in clearing away malaria and yellow fever from the Panama Canal zone A film was shown illustrating the great work of the Americans, in which the whole of the life history of the malarial parasite both in man and in the mosquito, was demonstrated A representation of the mosquito sucking blood from a patient was shown this film was lent by the courtesy of Dr Andrew Balfour of the London School of Tropical Medicine and Hygiene Various methods of controlling malaria were illustrated, including the rendering of houses mosquito-proof and the therapeutic use of quinine Cinematographs were also exhibited showing the process of emergence of adult mosquitos from pupa cases

Anderson College of Medicine Glasgow

The formal opening of the winter session at the Anderson College of Medicine took place on Tuesday October 14th, when an address was given by Dr Andrew Balfour C M G, director of the School of Tropical Medicine London There was a large attendance of students and the general public, who listened with the greatest attention and interest Dr Balfour chose as the title of his address "Vistas and visions—some aspects of the Colonial Medical Service" He gave a comprehensive survey of the great field for research in tropical diseases and indicated the wide range of opportunity for interesting and important work afforded in the Colonial Medical Services He described the many different diseases which would be met with in a tour of the tropics, pointing out the great need for continued research into the etiology of these, several of which were still obscure He instanced particularly bubonic plague, which continued to take a heavy toll of human life in India, the Gold Coast, Ashanti, and Nigeria, despite

their increasing knowledge of the bacillus and its carrier, the rat The campaign against rats had been pursued with relentless vigour, but without success in coping with the disease French workers on the African west coast had explained this by the possible presence of healthy human and of healthy cattle carriers of the disease Dr Balfour referred also to the outbreak of what might be called a new bacillary disease associated with ulceration of the throat in Egypt In speaking of leishmaniasis, he pointed out that though Sir William Leishman discovered the malady and its protozoal origin many years ago, they were still ignorant how the parasite effected a lodgement in the human body He emphasized the fact that the primary need for medical workers in the tropics was a microscope—that, indeed, this instrument there was as valuable as a stethoscope, if not more valuable

England and Wales.

Central Midwives Board

The Central Midwives Board for England and Wales met on October 9th for a special meeting and the ordinary monthly meeting Sir Francis Champneys presided

As a result of communications from the Ministry of Health the Board amended the first paragraph of the note at the back of the form of sending for medical help (Rule E 23 (*a*), page 31), to read

> "The medical practitioner responding to a call *in the case of any emergency, as defined in the Rules framed under Section 3, I (c) of the Midwives Act, 1902 (see Rule E 20)* will be paid his fee by the Local Supervising Authority for his attendance on this case, in accordance with the scale prescribed by the Ministry of Health"

A resolution was adopted requesting each local supervising authority to supply the Board with answers to the following questions

1 What drugs and antiseptics (including prophylactic drops for eyes) are carried and administered by the various midwives in your area?
2 What number of midwives practising in your area use "preparations containing opium" as permitted under the "Dangerous Drugs Regulations"?
3 Do you give any directions regarding the use of drugs by midwives in your area? If so, state what they are
4 Have any cases come to your knowledge in which a drug has been wrongly used? If so, state date, occasion, and result
5 Are any lectures or other forms of instruction arranged for midwives in your area regarding the use of such drugs and solutions as may be required in practice the conditions which call for their use, the mode of their administration, and their dangers?

Annual Medical Service in Liverpool

The annual medical service took place in St Luke's Church, Liverpool, on Sunday, October 19th There was a good attendance of medical men, a minority only being in academic dress The Lord Mayor and Lady Mayoress were present in state The University was represented by Vice-Chancellor Adami and many past-presidents of the Medical Institution were present The Bishop of Liverpool, Dr A A David, preached the sermon, taking as his text John i, 12 At the outset he drew attention to the impossibility of translating exactly the Greek word into a corresponding word in English The authorized version used the word "power," the revised version "right" The Greek word might be best paraphrased by "permission, and power to obtain" His discourse dealt with the efficacy of prayer and its helpfulness in all the straits that beset the life of man In becoming sons of God the endeavour should be to help one another by encouragement and by confidence in achieving the high ideals set before mankind through religion The offertory, which was on behalf of the Royal Medical Benevolent Fund, amounted to £81 12s 1d The local honorary treasurer will be pleased to add to this amount donations of members who were unable to be present, and Dr J E Nevins, 32, Princes Avenue, will gratefully acknowledge their receipt

The Liverpool Medical Institution

The first meeting of the eighty-sixth session took place on October 16th There was a large attendance of members and associates, and the President, Mr R C Dun, F R C S, delivered an inaugural address on "The banner of our pride" After an allusion to the untimely death of his predecessor, Mr G P Newbolt, he said that the number of members was now 486, that the library had quite recovered from the starvation period due to the great war, and drew attention to the Endowment Fund instituted for its maintenance Mr Dun's address was an historical survey of the origin, progress, and vicissitudes of the Knights of St John of Jerusalem A religious militant order, it was founded in 1048, and its object was to protect the holy places in Palestine The knights hospitallers played an important part in the Crusade, and for some centuries their chief seat was the island of Malta Through dissension and persecution the English contingent settled in Clerkenwell, where the knights hospitallers amassed great wealth, which was lost to them in the overthrow of the monastic institutions It never ceased to tend the wounded and sick in campaigns, but the Order practically became merged at the Geneva Convention in the Red Cross Society, whose beneficence and unexampled munificence was within the memory of all who had suffered during the great war It was the perusal of such stirring episodes intimately associated with the practice of first aid and medical treatment of the wounded that led Mr Dun to borrow from Macaulay the title of his address, "The banner of our pride"

Mr Thelwall Thomas proposed, and Dr Hill Abram seconded, a vote of thanks for an address which revealed much of painstaking research, and the members warmly acclaimed their appreciation of it Afterwards the President entertained the members to refreshments, and provided them with an excellent musical display

London County Council Report

The third volume of this report for 1923 is devoted to public health It includes the reports of Sir William Hamer as county health officer and school medical officer, both of which have been briefly referred to in this Journal (July 19th, p 125) In addition, the volume contains chapters (XXV, XXVI, and XXVII) dealing with general public health administration, main drainage, and housing Concerning tuberculosis it is pointed out that responsibility for its control in London is divided between the County Council and the metropolitan boroughs, the former providing or arranging for the residential treatment required through a public authority (other than Poor Law guardians), and the latter for dispensary treatment The total residential treatment in 1923 is represented by 1,173 beds occupied at the end of the year by insured persons and ex-service men, and 992 occupied by children and adults outwith the two above-mentioned classes Including both groups the admissions during the year were 5,326, in addition to 102 cases referred to the Invalid Children's Aid Association Permanent tuberculosis care committees, representative of statutory and voluntary organizations are in operation in nearly all the boroughs In connexion with the dispensary service the attention of the London Panel Committee and the British Medical Association has been called to the desirability of securing earlier notification The borough councils have been urged to arrange for tuberculosis officers being appointed visiting consultants for tuberculosis at Poor Law infirmaries in their areas There are now 31 tuberculosis dispensaries and two branch dispensaries in London Dental treatment is included in the service

For venereal disease the County Council and neighbouring authorities have a joint scheme for free diagnosis and treatment of in-patients and out-patients at 29 hospitals, and for in-patients only at 7 hostels Practitioners secure at the cost of the Council scientific reports on materials from suspected cases, and approved practitioners may obtain free of cost salvarsan or its substitutes Rescue and preventive work received attention by a central council of public authorities and voluntary agencies The provisions of Part I of the Children's Act, 1908, are duly administered, but the Council has been of opinion since 1920 that that part of the Act requires amendment There were 360 cases of puerperal fever and 753 of ophthalmia

1 P S King and Son, Ltd Royal 8vo, pp 148 2s 6d net

neonatorum, two cases occurred in which strong nitric acid had been put into the eyes of newly born infants by midwives in mistake for a weak solution of nitrate of silver, resulting in one case in total blindness of one eye and in the other of very great impairment of sight The Council has informed the Midwives Board of its opinion that the use of nitric acid by practising midwives should be prohibited Inquiry with regard to tuberculous milk is reported At four inspections of cows in London 7 370 cattle were examined, and no case of generalized tuberculosis was detected but in 125 cases other unhealthy conditions were found The action taken with regard to various diseases of animals, especially foot and mouth disease, is reported

In the chapter on main drainage, experiments in the biological treatment of sewage are briefly mentioned, and an account is given of administrative action regarding storm and flood relief The chapter on housing records the year's operations under the Act of 1923 in respect of many schemes

Employment of Married Medical Women

The General Purposes Committee of the London County Council is proposing to revert to the former rule whereby women doctors, like other women employees of the Council were compelled to resign their appointments on marriage In 1916, as a temporary expedient during the war, the rule was suspended, and married women continued in employment in various positions In 1921 when the rule was re-established so far as other women employees were concerned, it was thought desirable to make an exception for a further period of three years in the case of medical women in view of the difficulty experienced in obtaining practitioners with suitable qualifications The number of medical women at present employed in the service of the London County Council is 34 (17 of whom are part-time officers) and only three of these are married It is proposed to retain the services of the married women doctors now employed, as they have had valuable experience of school medical work, but to make the rule apply to medical women marrying in future

City of Westminster Health Society

Twenty years ago a society was formed for the improvement of health conditions in the City of Westminster ' and the annual report recently issued for the year 1923 shows that the society has cause for satisfaction It has seen the infant mortality rate decrease from 120 to 47 2 per 1 000 births since its activities began Last year the rate for London as a whole was 61 per 1,000 The work in maternity and child welfare includes visiting by salaried and voluntary workers, and the making of arrangements for pre natal examination and skilled attendance during confinement Instruction is given in mothercraft, with particular reference to the correct clothing of infants and school children Nasal hygiene receives special attention, and breathing exercises are taught at one of the centres where any form of nasal obstruction is sought out, and instruction given with regard to the use and care of handkerchiefs Students are encouraged to visit the centres maintained by the society, and during 1923 seventeen attended for practical training in various branches of the work The report contains a detailed analysis of the results of medical inspection of over a thousand children under school age It is recognized by child welfare workers that there is a dangerous and important gap between the infant welfare centre and the time when the child reaches school and again comes under regular medical supervision The medical inspection of the pre-school child has, however, received attention in Westminster and the report by Dr Olivier Richards is instructive The child is examined at each visit at intervals of one to three months, and advice is given to the parent concerning health and hygienic management It is emphasized that the welfare centre is not a treatment centre, and if some disturbance in health or physical defect is found the parent is advised what steps to take In the younger age groups the most frequent error in management is some wrong method of feeding, and the causes of difficulty in breast-feeding are analysed in detail While ' general conditions of the maintain breast-feeding, the large majority of these cases are not classifiable under the usual diseases contraindicating breast feeding, but are due to "insufficient rest" during the puerperium and to misgivings " and lack of confidence on the part of the mother or her relatives both these factors should respond to education In the older children (2 to 5 years) the chief error discovered is defective hygiene and the society is doing good work by teaching parents the importance to the child's health of fresh air and daylight, correct clothing, cleanliness, and regular habits

Ireland.

Medical Organization in the Free State

Well attended meetings of the medical profession in the Free State have been recently held in Carlow Cork, Limerick, and Clare The meetings were addressed by the Irish Medical Secretary, and schemes of organization for each of the county and borough areas were arranged The units adopted for organization were generally the Poor Law Union and the Health Board areas At a meeting of the County Clare medical practitioners recently held in Ennis the following resolutions were passed unanimously

1 That this meeting of the County Clare medical practitioners is of opinion that there is an urgent need for thorough organization of the profession throughout Ireland that we believe that that is best done by the establishment of county medical associations with a central delegate body in Dublin and an executive such as the Irish Medical Committee

2 That the first requisite to organization is money and therefore we are prepared to contribute financially to any reasonable extent required and we are also prepared to pledge our fullest co-operation with the Central Committee even to the extent of resigning our public offices in a body in the event of the conditions of medical service offered being considered unsatisfactory

Milk Supply of Dublin

The establishment of municipal milk depots in Dublin, with the object of fixing a reasonable price for milk in the city has been suggested following the protest aroused by the action of the milk dealers in raising the price to 2d per quart Dr O Dwyer, a member of the borough commission appointed by the Free State Government to take the place of the dissolved corporation has stated that if the baby clubs in the city and the Infant Aid Society desired to extend their activities and organization and approached the commissioners with a view to being afforded special facilities the matter would receive immediate consideration The Infant Aid Society and the baby clubs, which are doing very good work in supplying milk at a low price in the various depots under their control are in receipt of a grant of £3 200 from the commissioners and also £3 200 from the Government to assist them in their efforts It would appear that the commissioners are reluctant to take the responsibility of running milk depots but are prepared to assist financially the further extension of the enterprises of the baby clubs and Infant Aid Society with regard to supplying milk to the poor

A Belfast Presentation

The members of the visiting staff of the Royal Victoria Hospital Belfast, presented Dr W Calwell and Dr H L McKisack, their retiring colleagues, with a handsome piece of silver each, and entertained them as their guests at the annual dinner of the medical staff Dr Calwell joined the staff as assistant physician in 1895 and Dr McKisack as assistant physician in 1899

Cork Water Supply

At a recent meeting of the Cork Public Health Committee the city analyst, in dealing with a sample of water taken from the River Fergus at Coachford stated that the water is similar to common untreated sewage The contaminations which produce the polluted water should be subjected to some form of treatment by sedimentation, or allowed to flow over carriers on a field before being allowed to run into any stream of small volume" The analyst stated that the Macroom Rural District Council was responsible for applying the remedy described The Committee decided [illegible] against the Macroom Rural District Council

Ballymoney Board of Guardians

Arising out of a dispute with regard to the inadequacy of the remuneration allowed by the Ballymoney Board of Guardians for the *administration of* anaesthetics in the union hospital, Dr Wallace, medical officer of the Castle-quarter dispensary district, wrote to the guardians stating on behalf of the doctors who attended the recent conference that none of them would be available to anesthetize or assist at operations after October 2nd, 1924 The clerk said he had sent a copy of the letter to the Ministry, and had received the following reply

"I am directed by the Ministry of Home Affairs to acknowledge *receipt of your letter of the 27th inst respecting the refusal of certain medical practitioners in the* Ballymoney Union to assist at operations in the Route district hospital, and to state in reply that if the medical officer of the hospital requires assistance and the case is urgent, you should endeavour to obtain the assistance of the nearest available medical practitioner who is willing to act, at the best terms possible If the case is not urgent it is the duty of the medical officer of the hospital to apply to the committee of governors for authority to obtain the necessary assistance"

India.

School Medical Inspection in Simla

The quarterly report for the period ending December 31st, 1923, of Captain J R D Webb, I M S, the medical officer of Simla, embodies an account of the new system of school medical inspection introduced by him in the previous September Thus, out of 1,636 boys examined, no fewer than 1,111 (67 per cent) required some form of treatment, skin diseases were accountable in 233 cases, tonsils in 214, and glands in 287 Defective vision was found in 67 boys and defective hearing in 53 The application of the system had already resulted in an appreciable fall during each succeeding month of the number of boys suffering from various diseases Captain Webb proposes to make an addition to the system by the provision of expert medical assistance in the diagnosis of diseases of the eye, ear, nose, and throat, and by the organization of instruction classes in hygiene for both masters and children The results of medical examinations are recorded on index cards and accompany any boys who are transferred from one school to another He advocates the extension of this scheme to include schools for girls

Lady Reading Hospital, Simla

The announcement of the formal opening of the Lady Reading Hospital in Simla, on April 25th, appeared in our columns of May 17th (p 881), and the first patients were admitted without delay In the first four months of its existence 427 patients have been treated, 69 maternity cases dealt with, and 66 major operations performed The marked popularity of the institution indicates the extent of the need that is being met The hospital starts free from debt and with a sufficient endowment for its present needs The Simla municipality is co-operating cordially in the scheme and is represented on the hospital's governing body

National Baby Week, 1924

The report of the central executive committee of National Baby Week in India in 1924 contains a record of the successful venture launched by the Countess of Reading in August of the previous year The original committee appointed by Her Excellency included representatives of the Lady Chelmsford League for Maternity and Child Welfare and the Indian Red Cross Society, and these two societies jointly guaranteed sufficient funds for the project No general appeal for public subscriptions was required, though the scale on which the scheme was ultimately organized proved to be much greater than was anticipated Local governments, corporations, social welfare organizations, and private individuals contributed generously, and the committee was able to close its accounts without calling upon the two guaranteeing societies to any great extent The success of baby weeks in the various centres has made it clear that their annual repetition is desirable, each locality selecting the date most convenient to itself Several valuable conferences of health workers were held during the 1924 Baby Week, and will probably be increased in number during the coming year The report includes a short summary of the reports from many of the towns concerned, programmes of events and competitions, and suggestions put forward for the future The numbers of visitors in several towns were embarrassingly large, but the educational value of the whole undertaking was convincingly demonstrated

Correspondence.

THE BRACKENBURY TESTIMONIAL

Sir,—May I ask the hospitality of your columns to convey my most hearty thanks to those members of the profession who subscribed to the gift presented to me on Wednesday last? I have, of course, been able personally to thank only a few, but I hope that through them my thanks may have been conveyed to many others I should wish, however, that all, without exception, might know how very much I value their kindness, appreciation, and encouragement—I am, etc,

H B Brackenbury

Stroud Green, N Oct 20th

*** We publish in the Supplement this week a full report of the speeches made at the presentation on October 15th

DANGER OF STRONG APPLICATIONS IN THE PROPHYLAXIS AND TREATMENT OF OPHTHALMIA NEONATORUM

Sir,—May I, through your columns, draw the attention of practitioners to the danger of continued use of strong applications in cases of ophthalmia neonatorum? Every year since St Margaret's Hospital for ophthalmia neonatorum in London has been opened by the Metropolitan Asylums Board there have been admitted two or three cases in which both corneae have been destroyed or very severely damaged by the use of mercury perchloride in strengths of 1 in 500 to 1 in 3,000 used four or five times a day, or by silver nitrate (10 or 20 grains to the ounce) used as drops two or three times a day Although these drugs properly applied in correct dilutions are satisfactory, there is great danger if they are not properly used I therefore generally teach classes of midwives, etc, who attend this hospital to use protargol 10 per cent or acriflavine 1 in 1,500 in castor oil, as both safe and effective in the prophylaxis and treatment of the disease—I am, etc,

M S Mayou

London, W, Oct 16th

THE MADRAS GOVERNMENT AND INDIGENOUS SYSTEMS OF MEDICINE

Sir,—Three years ago the Government of Madras, at the instance of the Madras Legislative Council, appointed a committee to inquire into and to report upon the question of the recognition and encouragement of indigenous systems of medicine in vogue in the Madras Presidency The whole question was discussed fully, fairly, and crushingly in the issue of this Journal dated September 15th, 1923, from which I venture to quote the last two paragraphs

"The opinion is expressed in the report that no Western scientist should think of criticizing Ayurveda until he has learnt the Sanskrit language and studied the subject for some years under a competent Acharya But the Western scientist has no need of any such prolonged and detailed study he will, without the least difficulty recognize the familiar features of the phase of development reached by Ayurveda, when he recalls the history of his own science Similar unsupported metaphysical aid theoretical dogmas were to be found in both The 'authority of the Scriptures' was regarded as equivalent to the truth in the one as in the other, and our grandfathers accepted without a doubt the account of the creation of the universe given by Moses and regarded the first chapter of Genesis as the word of God In the last *hundred* years science has emerged from the metaphysical stage into the clear light of positive knowledge, and *if the Madras Government has the interests of the Indian people genuinely at heart, it will expend its energies in planting modern science in the country by the agency of scientific and teachers trained in Western methods, instead of endeavouring to stimulate the belated indigenous systems into renewed activity*

'There are many indications in the report that Ayurvedists feel the need of European methods—the microscope, bacterial techn[illegible]

etc What they really need is an altered scientific outlook they need to understand the difference between metaphysical and positive knowledge between the study of facts through the colour glass of theological dogma and their study in the plain daylight of science *The Madras Government is applied with the parties of the* It will be interesting to see whether it decides to set this country on the path of progress by the encouragement of European methods or pushes the country back into the old metaphysical rut [The italics are my own]

Most unfortunately the Government of Madras has not seen fit to adopt the excellent advice tendered to it in the above paragraph and has now, to the consternation of its medical officers, decided to constitute a Board whose functions will be as follows

(1) To form an association of practitioners of the indigenous systems *on the analogy of the British Medical Association* [Again the italics are mine]

(2) To formulate detailed proposals for a school or college of Indian medicine to be started in Madras

(3) To report whether, instead of the starting of a Government school or college scholarship may be given in certain existing institutions"

It is of the first importance that young medical men in this country should clearly realize the implication of this astounding order before they venture to enlist themselves in the service of a Government in which such things are possible The chief systems of indigenous medicine in the Madras Presidency (the Ayurvedic and the Unani systems) have been so well described in the article of September 15th 1923, already alluded to that it would be a work of supererogation to deal with them at any length here Their physiology is that of the so-called 'humours' their pathology resembles that which was current in the time of Hippocrates—a pathology which all other civilized peoples have for centuries cast behind them Their views on drugs are primitive, they know nothing of their standardization and rely rather on the phase of the moon under which the plants are gathered, or the dung of the sacred cow, on virgin's urine, and on similar harmful trash Western medicine has nothing to learn from them that it has not long ago learnt, classified, and standardized I can find no attempt in the report of the committee appointed by the Government of Madras to prove the hypotheses on which the whole of this archaic and effete system of medicine is supposed to be based A glaring light is cast on the committee's mentality by the astounding claim it makes that the ancient sages so trained their senses that their theories regarding the structure of the atom were not mere theory but were the result of direct observation and visualization by their highly trained senses Could credulity plumb a more abysmal depth than that which this claim reveals

Unfortunately this question of the State recognition by the Madras Government of this burlesque pretender to the claim of being a system of medicine does not stand alone For many years past the relations of the Madras Government with its medical officers has on a number of occasions been far from a happy one, and quite recently there has been a great feeling of discontent and annoyance amongst the medical officers now serving, with regard to the management of the big Presidency hospitals The Government, which proposes to launch out into expenditure on an effete and hopeless system of medicine has been issuing stringent orders as to the cutting down of the diets and of other items of expenditure in the very important Presidency hospitals My information is to the effect that those orders have not met with the approval of the officers of the institutions concerned, and that the opinion is widespread among them that if they are carried out the efficiency of the hospitals will be seriously diminished The matter attained such proportions that a number of articles appeared in the newspapers, criticizing the policy of retrenchment which had been followed, and in order to defend itself the Government issued to the press in July of this year a defence of its policy, in which it was stated that orders had been passed on several of the recommendations for effecting retrenchments "in consultation with the superintendents of the hospitals" I do not doubt that the superintendents were consulted, but was any respect or attention shown for their opinions? I have reason to doubt whether there was

There is a further statement in the Government's defence which has caused very deep and wide spread indignation in the ranks of the Service It is said "that people ever encouraged to resort to the Presidency hospitals of Madras not only with a view to medical treatment but in order to enjoy the amenities which hospital life afforded" As a superintendent of one of the institutions in the past I have read this statement with incredulity and indignation and find it difficult to find suitable terms in which to characterize it The work and the repute of the hospitals have gone out into all the world their diseases were drawn up by men who knew what the medical need and who recognized in them on times were incapable of doing how very much the success of medical and surgical treatment depended on carrying on hand in hand generosity in the diets given to really sick patients But it must be remembered that these hospitals are in the heart and centre of a population of forty million people and that into them are poured a large proportion of the difficult and desperate cases from all the district of the Presidency An added sting has been given to the order by the fact that the recommendation for the cutting down of the diets have been made on the advice of an inspecting officer who, whatever his admirable qualities may possibly be has I believe no qualification that would entitle him to registration in Great Britain, whilst he officers in charge of the Presidency hospitals are admittedly the pick of the local branch of the Indian Medical Service It is not even as if there were no fully qualified medical Indians in Madras for there are very many That there may be room for economies in minor matters no one will be prepared to dispute, but the suggestion that patients are encouraged to resort to the hospital to enjoy a loaf in luxury may certainly in my time—and I cannot doubt still is to-day—unfounded in fact, damaging to the reputation of the officers concerned and regrettable in the highest degree *If this is the way that the Madras Government is going to write in the press of its medical officers* who are by virtue of their position debarred from replying in their own defence it will have little cause to wonder if the young British born doctor turns his back on service in the Southern Presidency and this apart altogether from the merits or demerits of the proposed retrenchments

The much larger question that with which I have opened this letter—namely that of the recognition and encouragement in India of a so-called system of medicine for which a man trained in Western methods can have nothing but pitying contempt It knowing of this new and retrograde movement he enlists in the service of the Government, he will find it difficult indeed to avoid being made an instrument for the carrying out to some extent at least of a system of medicine which cannot fail to redound to his discredit and to damage his reputation This is no idle fear for several of the senior officers now or recently serving have been called on by Government to help them in this task and my information is that they have indignantly declined Will the man who goes in with his eyes open have the same liberty of action as the pioneer men who entered at a time when such a departure on the part of Government was undreamt of and if suggested as a possibility of the future would have been laughed at as grotesque and ridiculous

It is very difficult indeed to believe that the members of the Madras Government can really believe in this fantastic system of so-called medicine Are we to conclude then that they have yielded to Indian clamour and that they are acting in defiance of everything which a educated men know and believe, or is the explanation to be sought in the assumption that now that medicine is a transferred subject under an Indian Minister the latter has the last word in such decisions, and his European colleagues are practically powerless?

Whichever is the explanation I would ask once again Is it wise for the young British medical man trained in modern methods to enter the service of a Government in which such fantastic experiments are possible? The emphatic answer of the British Medical Association should, in my opinion, be in the negative, and should remain so until there is clear evidence that such retrograde and deplorable experiments are in some way made impossible

One last word We have trained a large number of medical men in our Indian colleges Many of these have taken degrees which deservedly stand high, and which entitle them holders to a place on the British *Medical Register* Are these men going to stand idly by and raise no protest against what both their intelligence and their heart must condemn? I sincerely trust they will not Those of us who have helped in the past to make them what they now are will look to them to justify our expectation that they will prove not unworthy of what Western science has taught them — I am, etc,

London, W, Oct 15th R H ELLIOT, Lieut Colonel I M S (ret)

THE REAL DEATH RATE

SIR,—The erroneous notion still exists, as has recently been revealed in articles in several leading newspapers, that the death rate by itself is always a fairly reliable measure of the health of a people I have thought for some time that we might be able to give the public a simple means of avoiding this and other fallacies on the subject The erroneous notion that if the inhabitants of two countries have a different death rate they must therefore have a different average of health is doubtless connected with the other common fallacy that 1,000 divided by the death rate (per thousand) invariably gives the average duration of life To estimate the average duration of life one must, of course, consider not only the death rate, but also the survival rate, if any—the survival rate being the rate of the natural increase of the population, that is, the birth rate *minus* the death rate, one must divide 1,000 by the death rate *plus* a fraction of the survival rate I have found that nine-twentieths is the fraction which gives an estimate most closely approximating to the result obtained by logarithms But ten-twentieths gives an estimate which is perhaps sufficiently close, and a half is an easily remembered and easily worked fraction I wish to suggest, therefore, that the death rate *plus* a half of the survival rate (D + ½ S) might be universally regarded as the real or comparable death rate of a country Dividing 1,000 by the death rate only gives a close estimate of the average duration of life when the birth rate and death rate are actually or nearly equal but dividing 1,000 by D + ½ S always does approximately give the average duration of life, so from this one would seem to be justified in regarding D + ½ S as the real death rate of a country

If my suggestion were approved and adopted, people could easily and quickly make a sufficiently accurate comparison of the average health in different countries, and thus avoid, for example, the frequent error of suggesting that France has a much higher mortality than England People could also be taught that 1,000 divided by D + ½ S gives an approximate estimate of the average duration of life, and therefore that D + ½ S cannot be under 15 unless it is possible for the inhabitants of a country to have an average duration of life of over 66 years, and newspapers would cease to publish articles suggesting that countries may come to have a birth rate and death rate of 6 per thousand, as this would at once be seen to imply the possibility of an average duration of life of about 166 years —I am, etc,

London, S W, Sept 27th B DUNLOP

THE BLOOD IN MILD CASES OF MALARIA

SIR,—In a recent work on haematology this sentence occurs in the description of a coloured plate illustrating tertian malaria "In view of the recent and moderately severe infection, the red cells show no anaemic changes" My experience of four relapsing cases is that no paroxysm is so slight as not to excite anaemic changes And, by the courtesy of asylum medical officers who supplied slides from several other cases, I am able to add that no case is too recent to escape such changes I saw no quartan or subtertian infection, but should expect the same changes in these

It is necessary to recall a few facts of haematology Polychromasia is a sign of unusually active erythrogenesis, and is conspicuous in the blood of the newborn babe, where it is associated with nucleated reds In adults polychromatic erythrocytes are still readily attracted into the blood stream and appear in minor anaemias of convalescents, whereas erythroblasts only appear in more serious anaemias or after severe haemorrhage In the so-called pernicious anaemias a toxin is also exciting the marrow to pathological regeneration The first indication of this is the appearance of punctated erythrocytes, which later on are associated with megaloblasts, giving a blood picture of anisocytosis, polychromasia, and normoblasts (normal regeneration), combined with punctate basophilia, Cabot rings, and megaloblast (pathological regeneration)

In malaria, as long as parasites are present in the blood I find erythrocytes showing polychromasia, anisocytosis, and often hypochromasia, and after each paroxysm punctate basophilia, Cabot rings, Jolly bodies, and sometimes erythroblasts In short, there is anaemia with unusually active normal regeneration, accompanied at the paroxysm with brisk pathological regeneration

At the same time leucocytes show neutropenia, monocytosis, and sometimes eosinophilia and plasmocytosis Amitosing lymphoid cells, myelocytes, and leucoblasts may usually be found after smart attacks Now myelocytes often accompany a sharp leucocytosis from any cause and may be compared to normoblasts But leucoblasts are quite pathological, and their entry into the blood is due not to chemotaxis but to direct toxic action on the marrow, so that they are comparable to megaloblasts Taken together, all four are characteristic of toxic anaemia such as the pernicious anaemias That toxins of varied origin may act on the marrow in much the same way is proved by the fact that small doses of lead soon produce a similar blood picture even to the leucoblast Obviously these toxins act mainly on the red, but also disturb the white elements of the marrow

These facts suggest that in suspected cases the presence of pathological regeneration may assist diagnosis in malaria just as in pernicious anaemia and in lead poisoning I do not know how long it persists, but it was still visible four and a half days after a paroxysm in which under treatment parasites had disappeared in forty hours, and of the erythrocytes 1 per cent showed polychromasia and 1 in 1,000 Cabot ring or punctate basophilia Punctate basophilia is entirely pathological and demands investigation just as much as albuminuria or glycosuria In any case it is useful to recognize these changes

With regard to technique, the following note may be useful

For leucocytes Leishman stain is satisfactory but more often than not it misses basophilia, Cabot rings, and Schuffner's dots in erythrocytes Manson's methylene blue answers well when made polychrome by boiling gently over a small flame for one minute about 8 c.cm in a clean test tube On cooling add 2 c.cm of the original solution, and it is ready for use and will keep for months It is convenient to have two small wide mouthed bottles with glass stoppers One contains 20 c.cm of pure methyl alcohol, and films are dropped in to be fixed by laying the bottle on its side for three minutes or more It may be used daily for months The other contains an ounce of distilled water, and five drops of 1 per cent aqueous solution of eosin and two drops of polychrome Manson's blue are added and mixed for each examination Fixed films are transferred with forceps to stain for half to two hours or longer—washing cautiously if overstained Films stained by Leishman in the usual way may, after examination of part of the film, be further stained in above solution with fair results Distilled water drop tube, and clean bottles are necessary and thin films desirable

—I am, etc,

West Ealing, W 13, Oct 17th ROBERT CRAIK, M D

GALL STONES AND CANCER

SIR,—I was surprised and pleased to see the letter from Dr Fiddian (September 27th, p 597) His views are much akin to mine I differ somewhat from him as to the nature of the cell affected, the epithelial cell is always the one affected, and it never forms a tissue—it lives its own life A letter of mine was published in the JOURNAL last year in which I said cancer was a reversion to embryonic condition This does not explain exactly what I mean I should have said the epithelial cell was arrested in its growth nearer to

the embryonic form than the fully developed cell Reversion to type is a term which is too loosely used the type is never lost, Nature is very "careful of the type" What I believe is meant by reversion is a casting off of adventitious accretions when the external stimulus which called them into existence has ceased to act I agree with Dr Iddian when he says it is clearly a struggle for existence on the part of the epithelial cells when faced with a new and menacing addition to their environment and it is the product of the cells which die in the fight which causes all the trouble in cancer, as shown in the later stages of Dr Leitch's experiments The epithelial cell knows no boundaries When the nature of cancer is officially recognized I believe my views will not be very far out —I am, etc,

Boston Sept 26th A W CRAWFORD

BLOOD TRANSFUSION

SIR —At the Annual Meeting of the British Medical Association at Bradford Mr Geoffrey Keynes read a paper on blood donors In the discussion he states (BRITISH MEDICAL JOURNAL, October 4th, p 615) that the citrate method is the most suitable for general use and that no further advance of importance has yet been recorded

When in Paris in March 1924 I saw at the Hopital St Michel a method of blood transfusion which I think is an advance in technique of some practical value The apparatus consists of a glass syringe of 200 c.cm capacity with an eccentric nozzle The piston contains in the distal part a small hollow fenestrated box, a screw inside the rod of the piston regulates the volume of the box which is filled with a mixture of sterile vaseline and paraffin By moving the piston up and down an even coating of the mixture is deposited on the inside of the glass barrel The syringe, piston, vaseline, and needles can be kept ready sterilized in a hermetically sealed drum With this instrument blood transfusion is very much simplified whole and not citrated blood is given clotting is delayed for a sufficient period, and the whole operation is reduced to two punctures

The instrument was designed by Dr A Becard and is made by Vincent in Paris Details of the technique and apparatus can be found in the recently published book *Transfusion du Sang*, by Victor Pauchet and A Becard — I am etc,

London W1 Oct 6th. STANFORD CADE, F R C S

MEDICAL OFFICERS AND CONSULTING FEES

SIR,—Dr Pearce thinks that I am chasing a shadow He is right The shadow I pursue is merely that intangible and elusive thing—professional status It is because, rightly or wrongly, I believe that the Bradford resolution was rather an oblique attack on that status, than a direct one on the few guineas we may receive as consultants that I, for one, regard it, like Dr Walker, as "provocative and unnecessary," and ask for its cancellation

As "Whole Time" wrote in your issue of September 20th we "stand or fall on our specialized knowledge" If we have none, we are fraud If we possess any it should be available for all, rich and poor There are still some people who will not accept gratuitous service If there are public authorities so short-sighted as to use the acceptance of these occasional consulting fees as an argument for the reduction of salaries—a phenomenon which I will credit when I meet with it—we can, if it is considered essential, hand over such fees to, say the after care committees

Dr Pearce and I qualified within a year of each other and we are both old enough to remember that the biggest fights have always been on account of 'shadows" Witness the prolonged struggle which was necessary to procure full military rank for the medical officers in the army and Indian services Ask an old army medical officer what that "shadow" meant to him! Nobody—I least of all—will quarrel with Dr Pearce for his attitude Such things are matters of personal evaluation What to one man is merely the pursuit of a shadow may mean to another the salvation of his soul —I am, etc

October 12th. TUBERCULOSIS OFFICER

PETER LOWIS "CHIRURGEPIE"

SIR,—The note in your issue of October 18th about the first edition of this book is not correct Three copies are known to the writer—one in the Radcliffe Library Oxford, another in the library of the Royal Medical and Chirurgical Society of London, and a third in the library of the Royal College of Physicians of Edinburgh — I am, etc,

October 20th. WALTER HUPST, Librarian Royal Faculty of Physicians and Surgeons Glasgow

Obituary

JOHN HAMMOND MORGAN, C V O, M A, F P C S,

Consulting Surgeon to Charing Cross Hospital

WE regret to record the death on October 11th at his house in Connaught Square, of Mr John H Morgan consulting surgeon to Charing Cross Hospital and to the Hospital for Sick Children, Great Ormond Street

John Hammond Morgan was born on August 19th, 1847 His father, John Morgan, F P C S, was for many years one of the leading general practitioners in the West End of London From Harrow he went to Trinity College Oxford, and graduated M A in 1873 Like his father before him he studied medicine at St George's Hospital and obtained the M P C S diploma in 1872 and the Fellowship in 1876 He was for some years surgical registrar at St George's and assistant surgeon to the West London Hospital Later he was appointed assistant surgeon to Charing Cross Hospital and to the Hospital for Sick Children, and surgeon to the Alexandra Hospital for Hip Disease For some years he served as examiner in surgery at the University of Oxford and from 1902 to 1910 was a member of the Council of the Royal College of Surgeons In 1897 he was president of the Medical Society of London, and delivered the Lettsomian Lectures on "Surgical affections of the urinary tract in children" He drew up the catalogue of the museum at Charing Cross Hospital, and wrote many papers on surgical subjects On three occasions he held office in the scientific sections at the Annual Meetings of the British Medical Association In 1878 at Bath he was secretary of the Section of Surgery at the London meeting in 1895 he was president of the Section of Diseases of Children, and in 1908, at Sheffield, he was vice-president of the Section of Surgery

For the following account of Mr Morgan's career and personal character we are indebted to his friend and colleague, Sir HERBERT F WATERHOUSE, consulting surgeon to Charing Cross Hospital

To all who were students at Charing Cross Hospital from 1880 to 1905 the death of Mr John H Morgan will come as a distinct personal loss, because no one was ever so completely the students' friend and no one could have taken a greater interest in their sports societies and welfare than he who was always affectionately known to them as "Johnny Morgan" Morgan was essentially a man whom students admire, as he was a brilliant athlete at Oxford where he was president of the Oxford University Athletic Club, and won the inter-university three mile race three years in succession His prowess as a long-distance runner was the more remarkable as he was a man of short stature

Hospital appointments came to him in full measure at first he was surgeon to the Hospital for Sick Children Great Ormond Street, to the Alexandra Hospital for Hip Disease, and assistant surgeon to the West London Hospital To the writer Morgan's work at Charing Cross to which he gave such devoted service for a quarter of a century was well known, as for more than ten years he acted as his assistant surgeon No man was more scrupulous in his attention to his hospital duties or gave more loyal service to any charitable institution

Morgan was by no means a showy operator His surgery was that of the old school, and he had but little sympathy with what he termed "new fangled ideas" Among his maxims, which he was constantly impressing upon his students, were "Do just what is required and no more",

'Avoid meddlesome surgery", and, as regards the abdomen, "Get in quick and out quicker" He was, however, probably a better surgeon than he was generally held to be, because his results were distinctly good, and they, surely, are the true test of a surgeon's merit Morgan's greatest friend was the late Sir Frederick Treves, for whom he had unbounded admiration, and whose writings might almost be said to have been his surgical bible Private practice and no attractions for Morgan, and few men of his experience and standing ever made, I imagine, a smaller income Possessed of ample means, he rather shunned than encouraged private operation cases, and to my knowledge frequently passed them on to Sir F Treves On my venturing a mild protest on one occasion he replied 'I don't want the money, and Treves will do it better than I could" This was characteristic of the man and his modesty Another instance I may mention of Morgan's self-effacement was when the lectureship at Charing Cross Medical School fell vacant Morgan had, by seniority, the first claim to the post He requested me to convey to Stanley Boyd his opinion that it would be in the interests of the school that Boyd should be appointed lecturer in surgery, and that therefore he had determined to stand aside in Boyd's favour He was an excellent committeeman, and acted for many years as chairman of the committee of the medical school.

Morgan was a deeply religious man, a firm adherent of the Church of England, and a staunch Conservative He retired from the staff of Charing Cross Hospital two years before he had reached the age limit, partly on account of ill health, but chiefly, as he told me, to give a position on the senior staff to his then assistant surgeon, Sir F Wallis In spite of ill health and his age (70 years), in 1917 he undertook the duties of surgeon in charge of the Hopital Anglais at Nevers, and carried on until increasing ill health compelled his retirement Of all that he did for the students at Charing Cross it is impossible to write in detail For many years he was president of the Students' Club and a generous supporter of the athletic, football, and cricket clubs, and the man to whom every student turned in time of trouble He will long live in our memories at Charing Cross as one of the best friends, the wisest counsellors, and the most generous supporters the school has ever had

Sir Henry Gauvain sends the following appreciation

The death of Mr John Morgan will be felt by many with a sense of real personal loss He typified the old-fashioned surgeon—dignified, courtly, with a high sense of duty, a direct manner which concealed the kindest of hearts and the most generous of instincts It has been my great privilege to be intimately associated with him during the past sixteen years On the suggestion of the then Presidents of the Royal Colleges of Physicians and Surgeons he was nominated an original member of the honorary medical board of the Lord Mayor Treloar Cripples' Hospital, and by the unanimous vote of his colleagues was elected chairman of the executive committee of that board No one could have been more zealous in the conduct of the duties his position entailed As the more urgent calls on his time diminished he returned ever more keenly his interest in the work at Alton His visits were always welcomed by all members of the staff, whom he treated with an altogether charming courtesy and consideration, and by the patients, who regarded him with both respect and affection He was deeply interested in the advances made in the technique of the treatment of our patients, and, tenacious to the sound principles on which conservative treatment of surgical tuberculosis are based, rejoiced in all advances made on these lines An ardent sportsman and a distinguished athlete, his activities were limited of recent years by reason of a severe accident in the hunting field Nevertheless, till comparatively lately he managed to travel a great deal, one of his latest considerable journeys being taken with his friend, the late Sir Frederick Treves, to the West Indies Since his retirement gardening had been one of his great hobbies, and it was ever a pleasure to him to take his friends around the delightful grounds of his beautiful home at Buckleburry Common In these grounds he had laid out a miniature rifle range for the use of the villagers, and it was a delight to him to see how greatly this thoughtful act was appreciated A staunch Tory and an ardent patriot, it was a source of great pride and pleasure to him to play his part in the great war as medical chief of the Croix Rouge Hospital for wounded soldiers at Nevers while in his 70th year I shall always remember him with respect and affection as a staunch and loyal friend, kind and generous to a fault, likeable and lovable, the true picture of "a fine old English gentleman"

SIR ROBERT HENDERSON, K C M G, C B,

Major General A M S (ret)

Major-General Sir Robert Samuel Findlay Henderson, K C M G, C B, Army Medical Service (ret), died in Queen Alexandra's Military Hospital, Millbank, on October 5th, aged 65

He was born in Calcutta on December 11th, 1858, the son of the Rev Robert Henderson, senior chaplain in Bengal, and was educated at Bedford School, Fettes College, Edinburgh University, where he graduated as M B and C M in 1882, and St Mary's Hospital, where he spent the final year of medical study Entering the army as surgeon on August 2nd, 1884, he became lieutenant-colonel after twenty years' service, brevet-colonel on November 22nd, 1910, and colonel on January 2nd, 1914, retiring on December 26th, 1917, with the rank of major-general He had a long list of war services Sudan campaign, 1885, Suakin, medal with clasp, and Khedive's bronze star, Burma, 1885 89, medal with two clasps, North-East Frontier of India,-Chin Lushai expedition, 1890, clasp, Burma, 1891, Wuntho expedition, mentioned in dispatches, *London Gazette*, February 9th, 1892, clasp, North-West Frontier of India, 1857 08, Malakand, medal with clasps, South African war, 1901 2, operations in the Transvaal, Orange River Colony, and Cape Colony, Queen's medal with five clasps *In* 1907 he was appointed secretary of the Royal Victoria Hospital, Netley, and from 1908 to 1912 he was secretary to the P M O in India, Sir Francis Trevor On promotion, in 1914, he was posted as A D M S at Quetta, in 1915 he was transferred to the 17th Division, and on August 1st, 1915, he was appointed director-general of the New Zealand Medical Force, with the rank of surgeon-general, holding that post till his retirement He was appointed honorary physician to the King in 1910, in 1917 he received the C B, and in 1919 the K C M G Until the outbreak of the war in 1914 he also held the Prussian Order of the Red Eagle

In his younger days Sir Robert Henderson was a famous international Rugby forward He was in the fifteen at Fettes, he played in the Edinburgh University fifteen for four years (1877-81), for the last three as captain, and subsequently for Blackheath, when he gained his international cap for England in 1882, 1883, and 1885

ARTHUR HILL TREVOR,

Commissioner of the Board of Control

Mr Arthur H Trevor took so wide and active an interest in the work of the Board of Control, and was so unremitting in his efforts to ameliorate the conditions and to advance the treatment of persons suffering from mental illness, that his sudden and unexpected death occasions a public loss, and by it the Commissioners are deprived of a colleague of great personality, who was highly esteemed as a friend by each one of them

Born in 1858, he was educated at Winchester and at Corpus Christi College, Oxford He was called to the Bar in 1884, and for some years practised on the South-Eastern Circuit and at the Sussex Sessions Appointed secretary to the Commissioners in Lunacy in November, 1905, he rapidly acquired so close and deep an interest in his new work that it was no small satisfaction to him when, two years later, he was chosen to fill the vacancy on the Commission created by the death of the late Mr G H Uthwatt, who was the victim of a murderous assault by a patient during an official visit to a mental hospital which, though it was not the immediate cause of his death, had left him in impaired health Trevor did a prodigious amount of work, not only when on circuit with a medical colleague inspecting

institutions and paying other statutory visits to patients, but also in the preparation of reports memoirs, and other literary work on behalf of the Board, in all this he was most painstaking was never satisfied until he had looked up all available references and what he wrote was always lucid and scholarly He also accomplished a great deal of useful work as a voluntary member of various committees, extraneous to his official duties but in aid of the better understanding of mental disorders and the advancement of their treatment mention, for instance, may be made of the active share he took in the work of the Committee of the Medico-Psychological Association in connexion with Lord Justice Atkin's Committee upon Criminal Responsibility, before which, later on, Mr Trevor, in conjunction with one of his medical colleagues, gave evidence He also gave evidence before the Royal Commission on the Care of the Feeble-minded in 1908 and upon the passing of the Mental Deficiency Act and the constitution in 1913 of the Board of Control, he threw himself heartily into the thus widened sphere of action of the Commissioners

He was emphatically a powerful link between the professions of law and medicine An ardent admirer of the latter, he was acutely interested in the broader aspects of medical problems, especially such as those which came up for discussion at the Board, or at meetings of the Medico-Psychological Association and of the Medico-Legal Society at which he frequently attended These he delighted to have explained to him by his medical colleagues and by the members of the medical staffs at mental hospitals, with so many of whom his duties brought him much in contact, and, endowed with breadth of vision and a ready grasp of essentials, he was a tower of strength in promoting progress The link between the two professions—inherent, indeed, in the constitution of the Commission ever since its inception in 1845—which he was ever desirous to see strengthened, was perhaps specially exemplified in him by first his constant reference to the exact words of the statute and then his habitual endeavour, short of their actual infringement, to mould administrative action so as to conform, as far as practicable, to medical aspirations In this connexion his bent of mind humane and progressive, was conspicuous in his persistent efforts to secure legislation to facilitate the prompt treatment of mental disorder in its incipient and early stages Up to within a few days of his death he had been preparing with much zest evidence for the Royal Commission on Lunacy Administration and the Early Treatment of Mental Disorder, and at their first meeting a moving tribute to his memory was paid by the chairman Mindful of his active interest in their work and his manifest wish to co-operate more actively than the fulfilment of his official duties perhaps demanded, the Medico-Psychological Association in 1910 elected him as an honorary member—a distinction but sparingly conferred only once previously upon anyone other than a medical man C H B

BOLTON GLANVILL CORNEY I S O M R C S

Mr Bolton G Corney, distinguished in the Colonial Service, died on September 24th at his residence Nevern Square West Kensington at the age of 74 after having suffered for a long period from distressing cardiac complications He was the son of Mr Bolton Corney well known in literary circles in London sixty years ago Educated at a private school in Barnes he always desired to lead a seafaring life, especially among semi civilized islanders then concluding that his wish might be best attained by going out to the South Sea Islands as a doctor he studied at St Thomas's Hospital and received the diploma of M R C S in 1874 He became well acquainted with many of the groups of islands in the Pacific and finally settled in the Fijis, being among the doctors whose labours on behalf of the natives under the headship of Sir Philip Gordon, were eulogized in the article on those islands in the *Times* of October 10th He wrote some instructive papers in association with his line of work on the mysterious Easter Island and on the epidemics of the insular nations in the Pacific Ocean As chief medical officer of the Colonial Government of Fiji and president, for a time, of the Board of Health Mr Corney was enabled to superintend and issue reports on the native population, especially as to the question of their threatened extinction and on his return to England he was made honorary secretary for Polynesia, in the Epidemiological Section of the Royal Society of Medicine Mr Corney should be remembered for a highly instructive series of surgical instruments of the most primitive character which he presented a few years ago to the museum of the Royal College of Surgeons of England, which have been arranged and catalogued in the instrument room in that institution These instruments are no longer to be found in Fiji as thanks to Mr Corney and his associates natives educated on European lines have replaced the medicine men who gave these strange instruments to the donor, explaining the uses to which they were applied

We regret to record the death of Dr James Albert Gibson, M B E of Carisbrooke, on October 12th at the age of 59 Dr Gibson was educated at Edinburgh, and at King's College and University College, London He graduated M B C M Edin in 1889, and proceeded M D in 1897 In 1906 he obtained the diploma of public health R C P S I For the last fifteen years he had been medical officer of health for the rural district of the Isle of Wight and the urban district of East Cowes and held for some time the appointment of county schools medical officer He had been medical superintendent of the Joint Isolation Hospital since it was built and was the county director for the island for the British Red Cross Society He was chairman of the Isle of Wight Division of the Southern Branch of the British Medical Association, and an ex-secretary and ex-president of the Southern Branch of the Society of Medical Officers of Health During the war he served as specialist sanitary officer to the Portsmouth garrison from 1914 to 1919 and was honorary medical officer in charge of the Seely Red Cross Hospital from 1914 to 1917 He contributed various articles on public health matters to *Public Health* He leaves a widow and one daughter The large attendance at the funeral service included the representative of Princess Beatrice, President of the Isle of Wight Branch of the British Red Cross Society the Mayor of Newport, and representatives of the British Medical Association, the British Legion, the rural district council, and voluntary aid detachments

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on October 16th the degree of Bachelor of Medicine (B M) was conferred on J W Alden

Medico-Legal.

R v HADWEN

A RULE NISI was granted by the Lord Chief Justice, and Avory and Salter, JJ, in the King's Bench Division of the High Court of Justice, sitting on October 17th, calling on Dr W R Hadwen of Gloucester (who, on October 2nd, was committed for trial to the Gloucester City Assizes on a charge of manslaughter) to show cause why the trial of his case should not be removed to the Old Bailey Dr Hadwen was also committed for trial on a coroner's indictment

The court was moved by Mr St John Micklethwait, at the instance of the Director of Public Prosecutions who said that the ground of the application was that it was not possible to obtain a fair trial in Gloucester, and in support of this statement he read an affidavit by the Deputy Chief Constable for Gloucester shire which said that at an inquest on Nellie Christabel Burnham on September 12th, the coroner's jury returned a verdict of manslaughter against Dr Hadwen—it was believed by a majority of nine to three The foreman after the verdict was given, was alleged to have said to Dr Hadwen "I am sorry of course, you know I did not agree" Dr Hadwen was well known in Gloucester as a medical man and also as a public man The people of Gloucester were taking great interest in the case, and as many as 200 people assembled at the entrance to the police court and showed considerable feeling Dr Hadwen being cheered and the crowd singing 'For he's a jolly good fellow" The crowd showed hostility to the witnesses for the prosecution including Dr Ellis and all this had been reported in the public press During the small pox epidemic in Gloucester the inhabitants of Gloucester were practically divided into two camps The present prosecution had revived the old controversy, and was the subject of constant conversation and the exhibition of partisanship among the citizens As the grand and petty jurors for the coming City Assize would be drawn exclusively from Gloucester City, the deponent was of opinion that a fair and impartial trial could not at present be held in Gloucester

Sir E Marshall Hall, K C, on October 22nd showed cause, and pointed out that he only knew of two cases reported in which the prosecution had asked for the removal of a case from assize to the Central Criminal Court, and only in one of those cases was the rule made absolute

The rule was discharged

The Services

NAVAL MEDICAL COMPASSIONATE FUND

AT the quarterly meeting of the directors of the Naval Medical Compassionate Fund held on October 7th, Surgeon Vice Admiral Joseph Chambers C B C M G, R N, Medical Director General of the Navy, in the chair, the sum of £69 was distributed among the several applicants

Medical News.

THE Semon Lecture, which is given under the auspices of the University of London, will be delivered this year by Dr Guisez of Paris, at the house of the Royal Society of Medicine, 1, Wimpole Street, W, at 3 p m, on Thursday, November 6th, and not at 5 p m, as previously stated The subject of the lecture will be malignant disease of the oesophagus

A NEW course of post graduate lectures arranged by the Faculty of Medicine of the University of Sheffield commences on Tuesday next, October 28th, at 3 30 p m, and will be continued on subsequent Tuesdays and Fridays up till December 19th A course of six lectures on the history of medicine, by Mr George Wilkinson, F R C S, will be given in the University during the winter session the first, on Friday, October 31st, at 4 p m, is entitled "The Mediaeval Practitioner—Chaucer's 'Doctour of Physik'"

THE fifth and sixth lectures of the series of post graduate lectures on cancer will be delivered at 1, Wimpole Street, at 5 30 p m, on October 29th, by Mr Sampson Handley, on cancer of the breast, and on October 31st, by Mr R H Jocelyn Swan, on malignant growths of the kidney On October 27th, at the Hampstead General Hospital, two weeks' intensive course commences, including clinics, operations, and demonstrations in the mornings and afternoons, and lectures at 4 p m A combined course in diseases of children has been arranged, from October 27th to November 15th by the Paddington Green Children's Hospital, the Victoria Hospital, and the Children's Clinic A course in venereal disease will be held at the London Lock Hospital, Dean Street, from November 3rd to 29th From November 3rd to 28th a course in dermatology will be held at St John's Hospital for Diseases of the Skin A fortnight's course in proctology has been arranged at St Mark's Hospital from November 10th to 22nd Syllabuses of the courses may be obtained from the Secretary of the Fellowship of Medicine at 1, Wimpole Street, W 1

DR ROBERT BRIDGES the Poet Laureate, attained his eighteenth birthday on Thursday October 23rd Dr Bridges graduated M B at Oxford in 1874, and was elected a Fellow of the Royal College of Physicians in 1900 All members of the medical profession will wish to associate themselves with the congratulations and good wishes conveyed to him by his friends and admirers

THE annual dinner of Fellows and members of sections of the Royal Society of Medicine will be held on Wednesday, November 26th at 8 p m at the Hotel Victoria, Northumberland Avenue London, S W

A SERIES of eight lectures organized by the People's League of Health is being delivered at 11 Chandos Street Cavendish Square on 'The mind and what we ought to know about it' on Mondays, at 6 p m Tickets for the series may be obtained from the office of the League 12 Stratford Place W 1

THE fifteenth international post graduate course at Vienna will be held from November 24th to December 6th and will deal with children's diseases The subjects to be treated include tuberculosis, various nervous diseases exanthemata and erythemata diabetes and orthopaedics During the last three days there will be the usual class work Medical practitioners wishing to attend should communicate in writing with the secretary of the course Dr Kronfeld Porzellangasse 22 Vienna IX the fee is 500 000 kronen The sixteenth international course will be held from February 9th to 21st 1925 and will deal with diseases of the digestive organs A detailed programme will be issued shortly

THE annual dinner of the Cambridge Graduates' Club of St Bartholomew's Hospital will be held on Wednesday November 19th at 7 30 p m in the Grand Hall of the Hotel Victoria with Dr J H Drysdale in the chair

THE University of Bristol Association of Alumni (London branch) will hold its annual dinner on Friday November 7th at 7 45 p m, at Pagani's Restaurant Great Portland Street Viscount Haldane will preside Members of the University and past members of its associated colleges are invited to apply for tickets (price 8s 6d, exclusive of wine) to the honorary secretary Dr Elizabeth Casson, Holloway Sanatorium Virginia Water

THE Aberdeen University Club London, will hold its biannual dinner (which on this occasion celebrates the George MacDonald Centenary) on Thursday November 6th at 7 30 p m at Gatti's Restaurant Strand Dr Milligan 11 Upper Brook Street W 1 will be pleased to hear from graduates, past or present wishing to attend or to join the club

THE extensions to the Alton Cottage Hospital provided by the generosity of Mr and Mrs F B Summers of Froyle Hants in memory of their two children at a cost of £18 000 were formally opened on October 18th by Canon Causton in the absence of Major General the Right Hon J L B Seely The additions provide for sixteen extra beds quarters for the medical and nursing staffs operating theatre two private wards a separate block for x ray treatment and an out patients department A power house has been installed for lighting and heating purposes, and rubber flooring has been laid throughout The hospital was founded by Canon Causton's father

IN succession to the late Mr A H Trevor the Hon Herbert Crawshay Bailey, Barrister at Law has been appointed as Commissioner of the Board of Control

THE National Social Hygiene Conference for 1925 will be held in Cincinnati from November 19th to 22nd This conference marks the tenth anniversary of the founding of the American Social Hygiene Association, and it will be held under the joint auspices of that association and the Cincinnati Social Hygiene Society

THE Minister of Health is about to make Regulations for the purpose of preventing infection from the employment in and about farms dairies etc of persons suffering from pulmonary tuberculosis Copies of the draft Regulations which have been prepared for this purpose can be purchased under the description "Draft dated 17th October 1924 of the Public Health (Prevention of Tuberculosis) Regulations 1925 from H M Stationery Office Adastral House Kingsway W C 2 either directly or through any bookseller (price 1d) Any representations on the subject should be addressed to the Secretary to the Ministry at an early date

MR V WARREN LOW C B, F R C S was the guest of the Surgical Instrument Manufacturers' Association at the annual dinner at the Holborn Restaurant on October 10th In acknowledging the toast of the guests he complimented British manufacturers upon the very high standard of excellence reached by them in the surgical instruments they produced He considered that British manufacturers had not only kept abreast of the times but had presented to the world types, characteristics, and qualities which defied imitation

THE issue of the *Paris Medical* dated October 4 th is devoted to neurology, and contains the annual review of this subject for 1924 by J Camus Other articles in this issue deal with the modern treatment of meningitis writers cramp and the differential diagnosis of medullary compression and sclerosis

MORE than fifty medical practitioners from eleven European countries took part in a tour of the principal Italian spas organized by the Italian State Tourist Office, between September 18th and October 3rd Ten different spas were visited in a special first class train and the various points of general and clinical interest were demonstrated by the resident medical specialists Receptions and entertainments were arranged in Milan, Pomezia and Naples A second tour will be organized next year to include some of the more important Italian climatic stations in addition to the spas Further information may be obtained from the London offices of the Italian State Railways and Tourist Department, 12, Waterloo Place, S W

THE final report of the Departmental Committee on the use of preservatives and colouring matters in food has been published as we go to press The Committee was appointed in July 1923, by the Minister of Health and its interim report on formalichyde in meat was reviewed in our issue of August 16th, 1924 (p 289) The final report (which will be noticed in more detail in an early issue recommends that with two exceptions preservatives in the sense defined by the Committee should be prohibited in all articles of food and drink offered or exposed for sale whether manufactured in this country or imported The exceptions are (1) *sulphur dioxide* in sausages (up to 3 grains per pound) in jam (up to 0 3 grain per pound) in dried fruit (up to 7 grains per pound) in preserved whole fruit or fruit pulp (up to 5 grains per pound) in beer and cider (up to 5 grains per gallon) in alcoholic and non alcoholic wines cordials, and fruit juices (up to 3 grains per pint) and (2) *Benzoic acid* in coffee extracts (up to 3 grains per pound) in non alcoholic wines cordials and fruit juices as an alternative to sulphur dioxide (up to 5 grains per pint) in sweetened mineral waters and brewed ginger beer (up to 1 grain per pint) The Committee recommends that the use of preservatives so far as they are permitted should be conditional on the nature and quantity present in the article of food being declared in a manner prescribed by the Minister of Health It recommends also that the employment of copper sulphate to colour or preserve the colour of peas and other vegetables should be prohibited and that the Minister of Health should issue a schedule of colouring matters whose use is non injurious to health

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—not necessarily for publication

THE telephone number of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is Gerrard 2630 (Internal Exchange) The telegraphic address is

EDITOR of the BRITISH MEDICAL JOURNAL *Articulate Westrand, London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc) *Articulate Westrand London*

MEDICAL SECRETARY *Hitherto Westrand London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street Dublin (telegrams *Bacillus Dublin* telephone 4737 Dublin) and of the Scottish Office 6 Putland Square Edinburgh (telegrams *Associate Edinburgh* telephone 4361 Central)

QUERIES AND ANSWERS.

INCOME TAX

Book Debts

"R G C" bought a death vacancy but on the board being taken from March 1st, 1922 How should the purchaser's profits be calculated as regards gross receipts?

Strictly the gross receipts should be the total of the bills of fees chargeable for work done in the year to April 5th 1923 whether actually received or not It is obvious that this process is difficult to calculate as it involves detailed examination of probable bad debts and consequently some adaptation of the cash receipts total is being sought for to arrive the purchaser H I G C had taken over the debts the matter would have been simplified, as he could have included with the receipts for work done by him those for past years, but as he did not have

the debts over he has not the requisite information The inspector of taxes therefore suggests that to the cash receipts should be added the amount of the book debts owing to "R G C" at April 30th, 1923 This is *correct*, provided that that amount be reduced by a proper allowance for bad debts, but unfortunately "R G C's" statement does not show how much was owing to him at that date, as his accounts were sent out at the end of March It is not clear whether the total amount of bills issued at that date is ascertainable, if it is, the solution should be fairly simple—for example, an eleven months' account to that date could be struck, or the account taken to April 30th on the basis of including the April cash receipts and taking the outstandings at the end of that month as the March debts less cash received and less estimated bad debts for the eleven months An objection the inspector might raise to this is that it includes nothing for work done in April, 1923 unless paid for, seeing that accounts would not have been sent out by "R G C" for that month The inspector suggests that the outstandings at April 30th 1923, be taken at one fourth of the 1923-24 bookings (calculated as being receipts *plus* £80 bad debts) *plus* an estimate (three fourths of £80) for applications for debts surviving from quarter to quarter, *less* the amount of the April, 1923, cash receipts It will be unfortunate if "R G C" has not retained a note of the total of the March, 1923, accounts, as an eleven months' account is a solution preferable to estimating outstanding debts at April 30th, 1923, and then taking eleven twelfths of the profit so calculated, but if he has not retained that record we advise acceptance of the method proposed by the inspector, though our correspondent may be in a position to show that the practice improved in 1923-24, so that the cash receipts for that year give an indication of the previous year's outstandings, which is excessive and should be modified for the purpose to which he proposes to put that figure

Earnings from Previous Employment

"X Y Z" qualified in July, 1922, and had sundry earnings in 1922-23 and 1923-24, in May, 1924, he accepted a post at £360 per annum and has been assessed to income tax at £360 Can he average his earnings?

*** "X Y Z" is assessable in respect of his present office or employment and, though the matter is not entirely free from doubt in our opinion he is not entitled to bring into the average the earnings from previous employment Such a claim would be particularly difficult to maintain where the employment had been discontinuous, in which case the earnings of parts of a previous year would not produce "a fair and just" average for a year of continuous employment One point on the actual facts occurs to us, if "Y Y Z's" engagement dates from, say May 5th, 1924, then in respect of the year to April 5th, 1924, he is assessable in the sum of eleven twelfths of £360=£330 only so far as this employment is concerned

"H C" entered a practice as a junior partner drawing a fourth share of the profits, and inquires what his position is with regard to the deduction of his expenses incurred subsequently

*** For the period of the assistantship "H C" was chargeable in respect of his salary, and the amount of the salary was deductible as a business expense in computing the profits of the practice Subsequently his fourth share (which in a sense displaces the salary) cannot, but his expenses can be deducted in computing the practice profits Having arrived at these profits accordingly the three years' average is struck, and "H C" is liable for his share of the assessment so calculated, and further expenses cannot be deducted therefrom In other words, the expenses should be those incurred in the separate three years in the carrying on of the practice, not those of the year of assessment Having regard to the deductibility of the assistantship salary this is not likely to work out unfairly so far as "H C" and his partner are concerned

LETTERS NOTES ETC

HERPES ZOSTER AND VARICELLA

DR W N W KENNEDY (Hale, Cheshire) writes Early last month a married lady, aged 35, consulted me regarding an eruptive condition of her skin In the interscapular space, slightly to the left of the middle line, there was a herpetiform rash covering an area roughly equal to that of a half crown piece The pustules tended to become confluent, although their original discrete character could still be recognized There was also some suggestion of haemorrhage The condition was unassociated with pain however and there was no history of trauma or irritation No other portion of the skin surface was affected In a week the scabs had separated Exactly fourteen days from that date one of her children (aged 7 years), developed a characteristic chicken pox eruption without any systemic symptoms The family lives in an isolated house in the country The children had not been in contact with any other children, either at school or with visitors None of the adults, except the mother, gave a history of a recent skin affection The circumstances suggest something more than mere coincidence

MIXED GLANDS IN THE TREATMENT OF RHEUMATIC AFFECTIONS

DR A GORDON WATSON (Bath) writes In 100 cases of "rheumatic" arthritis in which a combination of the thyroid, pituitary, ovary, and testis were given by the mouth as an adjunct to other treatment, the following results were noted 70 felt some benefit from the tonic effect, 20 believed that mixed glands were the deciding factor in their marked improvement, and in 10 cases no difference was discernible The same preparation was used in all these cases, polyglandin (Allen and Hanburys) which contains in each teaspoonful of the elixir, pituitary 1/4 grain, thyroid 1/2 grain, ovary 2½ grains, testis 2½ grains of the fresh glands Great difference in individual tolerance was noticed—for example, in one patient, aged 79, half teaspoonful doses caused throbbing headache in the temporal region, but three drops thrice a day was highly effective, a fortnight's course (no other treatment being used) enabled this old gentleman to walk three or four times as well as before, his knees became more supple, and he has largely lost the fear of his knees giving way under him In some cases of rheumatoid arthritis and chronic "muscular rheumatism" this treatment seems to be of use, but my cases are not yet numerous enough to judge from, more especially as I have not used it alone

A RAY EXAMINATION IN RELATION TO PULMONARY TUBERCULOSIS

"GENERAL PRACTITIONER" writes to emphasize Dr F G Chandler's remarks (October 18th, p 742) about the danger of placing reliance on physical signs in diagnosing phthisis Early phthisis, he says must be diagnosed by symptoms, and just as important as tubercle bacilli, toxaemia and evening rise of temperature, is a weekly record of the patient's weight Examination of many thousands of specimens of sputum has also impressed me with the fact that failure to find the bacillus must not negative the diagnosis Many years ago, I well remember the late Dr Schorstein saying, "When you can diagnose phthisis by physical signs, you can do nothing for your patient" The early symptom of malignant disease of the larynx—hoarseness or loss of voice—is frequently neglected until the patient is past help At present no help or encouragement is offered to men wishing to do post graduate work, it has to be done in their leisure hours and at their own expense, also, for obvious reasons, resident posts in special hospitals are frequently given to men from the Dominions

FREE PASSAGES FOR UNIVERSITY GRADUATES

DR ALEX HILL (secretary of the Universities Bureau of the British Empire) informs us that the six great lines engaged in the passenger service to Australia and New Zealand have agreed to grant eight free first class return tickets yearly to university graduates desirous of studying problems connected with the development of the resources of the Dominions or of holding temporary teaching posts The selection of the recipients is to rest with a committee of the Universities Bureau, 59, Russell Square, London, W C 1

TELEPHONES FOR MOTORISTS

DURING the past month the Automobile Association has installed eight more day and night roadside telephones for the use of its members The "A A" roadside telephones are distributed throughout the country along the main roads, and access is given to the telephones by a special key issued to members The new telephones are *located at the cross roads* at Pulham, on the main Norwich-Ipswich road, at Flint House cross roads, on the Newmarket-Royston and Ware-Cambridge roads, at Blackmoor Gate, on the Lynton-Barnstaple and Ilfracombe-Wheddon cross roads, at Halcon Corner
Desford cross roads on the L
House cross roads, on the
roads, at Cadnam cross ro
road, and at East Horndon, on the new Southend road

DISCUSSION ON CARDIAC IRREGULARITIES

Correction

BY an oversight it was stated last week that Dr Langdon Brown was in the chair of the Section of Medicine of the Annual Meeting at Bradford when Professor Wardrop Griffith opened the discussion on cardiac irregularities The chair was taken on this occasion by the president of the section, Professor Arthur J Hall, of Sheffield

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 38, 40, 41 44, and 45 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 43, and 44

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 109

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

306. Hemiplegia in Typhoid Fever

G Tizianello (*Il Policlinico* Sez Prat, Aug 18th, 1924 p 1069) states that among more than a thousand cases of typhoid fever admitted to the typhoid pavilion of the civilian hospital at Venice in the course of the last seven years only two developed hemiplegia Only a few instances of this complication of typhoid have been recorded in medical literature all of which ended in recovery, so that it was impossible to determine the nature of the causal lesion Tizianello's first case occurred in a woman aged 29, who developed left hemiplegia followed by gangrene of the left arm in the third week of a severe attack of typical typhoid fever Death took place after about five weeks illness and the autopsy showed an area of softening in the basal ganglion on the right side involving the putamen part of the globus pallidus and internal capsule and a small portion of the external capsule The second case was in a girl aged 18 who on the fifth day after the temperature had become normal and on the thirtieth day of disease, complained of headache and a few hours later suddenly developed right hemiparesis Almost complete recovery eventually took place Tizianello regards the process as thrombotic in both cases He thinks that probably the primary cause of the hemiplegia is always typhoid arteritis The similarity of the two cases suggests that the typhoid toxins may have their seat of activity in the grey nuclei of the base probably the putamen

307 High Blood Pressure.

According to E Kylin (*Klin Woch*, September 16th, 1924 p 1712) the disturbance in the autonomic nervous system is the point to which treatment should be directed in cases of high blood pressure A rest cure should be tried first, since this often gives good results, though when the patient returns to his former occupation the pathological condition may reappear For some time the author has treated essential high blood pressure by calcium salts and atropine given by the mouth Theoretical grounds for this treatment are the supposed predominance of the vagus nervous system over the sympathetic nervous system in essential hypertonus (as indicated by the adrenaline reaction) and the view that the calcium ions bring about stimulation of the sympathetic system It has been shown also that in essential hypertonus the calcium of the blood is diminished By the administration of atropine the author endeavours to restore the equilibrium between the vagus and sympathetic nervous systems Four cases are recorded in detail illustrating the improvement under the administration of calcium chloride and atropine four times a day These patients were in hospital but similar improvement was obtained in out patients, and the author considers that the treatment is worthy of further trial

308 Three day Fever with Rash in Children

E Gla zmann (*Schweiz med Woch*, June 26th 1924 p 589) discusses the diagnosis of this condition, a comprehensive account of which was first published in 1910 by Zahorsky, who called it "roseola infantilis The author has studied it since 1918 in Bern, and publishes several case reports to illustrate its most salient clinical features The disease is practically limited to children between the ages of 6 months and 2 years It begins with three days of comparatively high fever the fall of which by crisis is rapidly followed by the appearance of a rash resembling that of scarlet fever, measles, or rubeola During the three days of fever the patient is restless, sleepless and obviously in pain children old enough to speak complain of headache In this pre eruption stage of the disease there is only one reliable guide to the diagnosis—a leucocyte count The author points out that it is remarkable that such a brief and mild exanthematous disease should have so profound an influence on the leucocytes Great leucopenia occurs associated with a marked relative increase in the number of the lymphocytes to 80-90 per cent of all the leucocytes The number of the polynuclear leucocytes both absolute and relative is greatly reduced and the few polynuclears which remain often show degenerative changes a few myelocytes and metamyelocytes may be found The relative number of the large mononuclear leucocytes is increased With regard to the infectivity of this disease the author has not seen it in more than one child of the same family at the same time, perhaps because the age limit of this disease is comparatively short

309 Abortion of Measles by the Serum of Convalescents.

S Buttersieser (*Deut med Woch*, June 27th, 1924, p 676) publishes several tables illustrating the importance of measles as a remote or immediate cause of death among infants in hospital Almost one sixth of all the deaths in a children's hospital during 1922 were due to measles contracted in the hospital He recommends the adoption of the Degkwitz system of injecting the serum of convalescents into children who have been exposed to infection, and who may possibly be in the early stage of the incubation period He reports the successful use of this prophylactic measure on several occasions According to him, as much as 100 c cm of blood can be taken from a convalescent child if not too young this quantity being sufficient for twelve children He urges the medical authorities to organize a system of collecting the serum of convalescents and to educate both the public and the medical profession as to its value Munich and Stuttgart have already organized the distribution of this serum, and Buttersieser maintains that if such organizations were ubiquitous thousands of infants could be saved every year

310 Epidemic Encephalitis in Sweden

E Bergman (*Hygiea* July 15th 1924 p 425) states that about 2 500 cases of epidemic encephalitis have already been notified in Sweden and that more than half of the cases occurred in 1921 January 1921, marked the culmination of the epidemic and there were as many as 520 new cases in this month About 500 cases were notified in 1923 A study of 67 cases in Upsala was made by the author who found that in about 50 per cent the onset of the disease was marked by vague febrile symptoms In no case was the onset insidious, and only in 2 cases were there general symptoms without fever at the onset In as many as 18 cases lethargy and paralyses of the ocular muscles occurred at the beginning of the disease The cranial nerves and ocular muscles were affected in 85 per cent and in most of these cases the lesions of the cranial nerves began very early Indeed in some cases the disease was first detected when the patient went to an eye hospital on account of diplopia Most of the facial paralyses passed off rapidly The amyostatic symptom complex or Parkinsonism was observed in as many as 29 cases Ten cases terminated fatally and only 15 of the 67 patients were cured completely, though another 10 patients recovered sufficiently to resume full work The prognosis was worse and the mortality higher for the hyperkinetic than for the lethargic cases It was often noticed that neurasthenic and psychasthenic conditions developed as sequels, and either insomnia or persistent drowsiness continued long after the onset of the disease The author expresses considerable pessimism with regard to the various methods of treatment tried

Surgery.

311 Congenital Duodenal Occlusion.

J M Smellie (*Brit Journ Child Dis*, July-September, 1924, p 192) records three cases of this rare condition which he has seen during the last year Two died within a few days of birth as is the almost invariable rule, but one case lived for nearly three months Only three cases on record have survived longer In Keith's case where the duration of life was nine months the autopsy showed that the occlusion was complete but in Buchanan's case which lasted for eighteen months, and in Cautley's case extending over twelve months, the atresia was incomplete The site of the occlusion in Smellie's first case was just below the opening of the common bile duct of which type there are about twenty three recorded cases and in the second case the duodeno-jejunal flexure was the site of occlusion of which type eleven instances have been observed In the third case the occlusion would seem to have occurred just above the opening of the common bile duct but in addition there had been a complete interruption in the continuity of the gut and the second part of the duodenum appeared to have a common origin from the junction of the common bile duct and the pancreatic duct No previous examples of this variety appear to have been described While a developmental origin appears to be the most probable explanation of the condition in the majority of cases some are probably due to a localized foetal peritonitis, or foetal volvulus, especially

those occurring at the duodeno jejunal flexure In favour of the developmental theory is the presence in a small percentage of cases of other congenital abnormalities One of Smellie's cases had an imperforate anus, and in another the gall bladder was absent Relief for the obstruction can only be obtained by operation, which was successful in cases recently described by Jewesbury and Page and Hutchison

312 Cholecystenterostomy

F G DU BOSE (*Surg., Gynecol., and Obstet.*, September, 1924, p 295) considers that the results of gall bladder surgery are unsatisfactory, repeated operations for recurrence being a reflection on surgical efficiency He records his experience with cholecystenterostomy in twenty cases covering a period of eleven years, and insists that since the gall bladder concentrates bile, secretes mucus, and is a reservoir, it should be conserved whenever possible Cholecystenterostomy has been considered hitherto an operation of necessity rather than of choice, it remains to be seen whether it may not be rather the operation of choice Du Bose considers that it is indicated in common duct obstructions in patients who are "poor surgical risks," also in jaundice secondary to diseases of the liver and pancreas causing common duct obstruction In perforated duodenal ulcer he finds that it promotes healing of the ulcer by bathing it continuously in the alkaline bile In cases of stricture of the bile ducts he prefers it to choledochotomy or plastic surgery, being simpler, safer, and equally effective The operative technique recommended is the formation of an anastomosis between the gall bladder and stomach round a rubber tube After the suturing is completed an omental graft is placed round the suture line for complete protection The anastomosis may be made between the stomach or the duodenum This operation is contraindicated in cancer of the gall bladder, in cases of gangrenous or atrophic cholecystitis, and also in the presence of cystic duct occlusion or obstruction due to causes other than stone

313 Depressed Fracture of Zygoma

J C LEHMANN (*Zentralbl f Chir.*, September 13th, 1924, p 2016) states that there are very few recorded cases of this injury Lehmann's patient was struck on the left cheek by an iron headed "life preserver" When admitted there was a depression over the zygoma as large as the tip of a finger, but there was no external wound nor could crepitus be felt No discoloration of the skin was present round the depression, and the pain elicited on pressure appeared to be so slight that it was difficult to believe that the injury had occurred on the preceding day Next day, however, trismus was present, due to the pressure of the depressed bone on the temporal muscle Under local anæsthesia a small incision was made along the upper border of the zygoma, through this opening the bone was explored and an elevator introduced, the depressed fragment was easily replaced and the patient was relieved immediately, as trismus completely disappeared A small metal splint was applied externally, but it was not found necessary to wire the fracture, as recommended by Matas There was no recurrence of displacement through the action of the masseter Lehmann remarks that it is impossible to reduce a fracture of the zygoma by manipulation with a finger in the mouth, as the temporal muscle is an obstruction

314 Intestinal Obstruction by Meckel's Diverticulum

K A ROMBACH (*Nederl Tijdschr v Geneesk.*, August 9th, 1924, p 776) states that Meckel's diverticulum, which is the result of incomplete obliteration of the omphalo enteric duct, is found 20 to 24 inches above the ileo caecal valve Albert saw it in 2 per cent of the bodies examined by him, while P Turner in 10,360 autopsies noted its presence in 81 cases, in 18 of which it was of pathological significance The symptoms caused by Meckel's diverticulum may be classified as follows (1) Those due to persistence of the duct and its permeability throughout its entire length (2) Those due to intestinal obstruction by intussusception or strangulation of the intestine by the diverticulum (3) Those due to infection or perforation of the diverticulum The definite diagnosis of Meckel's diverticulum being the cause of these symptoms cannot be made, and the possibility only can be suspected In a certain number of recorded cases appendicitis was supposed to be the cause of the symptoms Rombach records a case in a previously healthy man, aged 31, who developed symptoms of intestinal obstruction which laparotomy showed were due to strangulation of the ileum by a Meckel's diverticulum one inch long Symptoms of peritonitis developed the next day, necessitating a further operation, which showed that the condition was due to paralysis of the portion of the gut from which the diverticulum had been removed, but ultimately recovery took place.

Therapeutics.

315 Treatment of Tapeworm Infections

H JACOBÆUS (*Ugeskrift for Laeger*, September 11th, 1924, p 669) reviews his experience of 132 cases of tapeworm infection, 125 of which were due to *Taenia mediocanellata* and 7 to *Bothriocephalus latus* In only a few cases could such symptoms as colic, vomiting, and emaciation be definitely traced to the intestinal parasites, in most cases there were either no symptoms or the gastro intestinal symptoms present were unconnected with the worms In only one of the 7 cases of *Bothriocephalus latus* was there definite anæmia Since the life of a cestode may be a matter of twenty five to thirty years, he remarks that it is well to get rid of them and not to wait for their spontaneous expulsion or their death from old age With regard to the amaurosis recorded in about 100 cases treated with extract of male fern, the author notes that most of these cases occurred in South Germany and Switzerland In the Scandinavian countries no such accident has been recorded, although the extract of male fern is much used A common cause of failure of treatment with this drug is the vomiting it provokes, and Iacobæus has found that by giving veronal on three evenings in succession, before the male fern is given, the tendency to vomit is greatly reduced He gives phenacetin with the veronal, 6 grains of each being taken every evening To an adult 2½ drachms of the extract of male fern is given at 7 a m in a little wine At 8 30 a m a powder containing calomel and jalap is given, and at 10 a m a strong infusion of senna leaves, he thinks it well to give aperients for a couple of days beforehand By combining male fern medication with veronal and phenacetin in every case likely to be troublesome on account of vomiting, the author has considerably increased the proportion of cases in which the head of the worm was evacuated, in the period 1922–24 he treated 49 cases, in 40 of which the head of the worm was found

316 Serum Treatment of Anterior Poliomyelitis

F S CLARKE and A G DOW (*Journ Amer Med Assoc.*, August 9th, 1924, p 421) discuss the use of Rosenow's horse serum in the prevention of paralysis due to anterior poliomyelitis, and give brief accounts of six cases in which it was successfully employed They urge the necessity of recognizing this infection before the onset of paralysis, and attach special significance to the following diagnostic points pyrexia rarely over 101° F, neck rigidity, and inflamed tonsils and faucial pillars Hyperæsthesia and resistance to examination are also said to be important symptoms, Kernig's sign, if present, is suggestive, but its absence does not rule out the disease, and the patellar reflexes are usually exaggerated, but vary from day to day The authors do not consider that the cell count of the spinal fluid offers a reliable basis for diagnosis In each of the six cases reported rapid improvement followed the injection of Rosenow's serum, and recovery was complete without paralysis

317 Sulfarsenol in the Treatment of Congenital Syphilis

G ÅHMAN (*Hygiea*, August 15th, 1924, p 481), who is in charge of a Welander hospital for congenital syphilis in Sweden, points out that in such an institution it is impossible for the medical officer to give all the necessary injections of anti syphilitic remedies, and in order that nurses may give them they should not have to be administered by the intravenous route For this and other reasons the author has found salvarsan, neosalvarsan, and various other arsenical preparations unsatisfactory, but he has found sulfarsenol, a French preparation introduced by Lehnhoff Wyld, and closely related to neosalvarsan in its chemical formula, almost ideal Injected subcutaneously as a 6 per cent aqueous solution it causes little pain and does not leave a persistent infiltration The author has given about 300 injections to 26 children, 19 of whom had previously been treated with other preparations of salvarsan to which the disease had proved more or less refractory The success of the sulfarsenol injections was the more striking as most of the patients had shown themselves to be refractory to salvarsan

318 Tuberculin Treatment in Infants

R OSSWALD and H SCHONFELD (*Monatschr f Kinderheilk.*, August, 1924, p 413) have endeavoured to determine (1) the clinical results in young children of two of the specific forms of treatment for tuberculosis, and (2) the effect of the treatment on the cutaneous sensitivity of the patients to tuberculin (von Pirquet test) Pounder's method of vaccinating the patients repeatedly with a prepared serum was applied to 36 children suffering from tuberculosis of the lungs, lymph glands, bones, or abdominal viscera The results were watched for periods varying from three to eighteen months,

but no difference could be observed clinically between the patients who received this specific treatment and those who did not In the absence of clinical manifestations the authors tried to determine whether the reaction of the patients to the biological von Pirquet test showed any variation, and they applied the test to 23 children before, during, and after their treatment according to Ponndorf's technique In 15 cases the cutaneous sensitivity showed an unfavourable alteration, in 2 it was unchanged, and in the remainder there were minor alterations, first in one direction and later in the other Moro's method of inunction was applied to 22 children suffering from tuberculosis of the peritoneum, lymph glands, or lungs, and, as before, the patients were kept under observation for many months From clinical observations the authors were unable to convince themselves that the treatment had any therapeutic value They again resorted to the von Pirquet test, and found that in 17 out of the 22 children the local cutaneous reaction showed no definite change, in 4 it was altered unfavourably, and in only one case favourably It cannot therefore be said from these results that Moro's treatment has any effect on the cutaneous sensitivity to tuberculin

Dermatology.

319 Herpes Zoster in Hodgkin's Disease

H K PANCOAST and E P PENDERGRASS (*Amer Journ Med Sci* September, 1924, p 326) consider that herpes zoster is present in Hodgkin's disease with sufficient frequency to justify its inclusion among the skin manifestations of that disease Notes are given of four cases of Hodgkin's disease and one of ovarian sarcoma, in which an attack of herpes zoster occurred While a certain number of cases are the result of a propagated neuritis, the zoster being due to an inflammatory irritation of a nerve transmitted to the cutaneous elements along its distribution such a condition may also arise from compression by a tumour In secondary malignant disease of the spine and in new growths of the chest herpetic eruptions may appear along the course of the nerves involved in the compression In the first case of Hodgkin's disease a typical zoster on the right side lasting about eight weeks was associated with palpably enlarged glands in the right kidney region while in the second a severe right intercostal herpes occurred without any demonstrable mediastinal enlargement the disease being followed by keloid formation in the third case during a slight attack of left intercostal zoster the hilum shadows were enlarged and in the fourth the herpes was situated along the distribution of the right femoro cutaneal nerve without any glandular enlargement in the inguinal or pelvic regions In the case of ovarian sarcoma general peritoneal metastasis was found at operation and herpes zoster involving the left eleventh and twelfth intercostal and first lumbar nerves developed and lasted eight weeks x ray examination of the chest and spine being negative as regards evidence of a new growth The patient later developed a mediastinal metastasis, but improved under x-ray treatment in spite of the extensive involvement she was still alive In the four cases of Hodgkin's disease the severity did not appear to have any relation to the eruption which was probably due to irritation caused by the proximity of the glandular enlargement to the ganglion

320 Symmetrical Lines on the Back in Tuberculosis

OLGA ELIASCHEFF (*Ann de Derm et de Syph*, June, 1924, p 555) notes that cases have been recorded in which pulmonary lesions in young subjects have been accompanied by the appearance on the thorax of lines of reddish colour and that in the instances hitherto recorded these lines have been located on the side opposite to the pulmonary lesion She now reports a case of pulmonary tuberculosis where the lines were observed on both sides although the lesion was in the left lung There were nine rows on the right side of the back and six on the left they were symmetrical, and corresponded in direction with the zones of cleavage of Langerhans Internally they were limited by the vertebral column externally by the axillary border and they extended from the seventh rib above to a line drawn transversely three fingerbreadths above the iliac crest below They were disposed in oblique bands some of which were interrupted by areas of healthy skin their length was from a third of an inch to four inches their breadth was just over an inch The colour was bright red the surface finely folded the edges well defined Palpation gave the impression of a skin rather thin and soft through which blood vessels were visible in places The horny layer was poorly developed in parts and from some places the granular layer was absent where present the latter was represented by fine cells filled with minute granulations While pigment was lacking in the lesions the adjoining basal cells were richly pigmented The connective tissue appeared normal, but round the vessels of the chorion there was a dense infiltration, composed for the most part of round cells and of some epithelial cells and fibroblasts The elastic tissue in the papillae and the chorion was broken, and was so attenuated in the upper layers of the latter as to be represented by fine granulations but in the healthy parts it seemed to be a denser network than normally The hair follicles, sebaceous glands, and sweat glands were normal The author discards the theory of a mechanical cause for the lesions—overdistension of the skin—nor does she favour the view that the condition may result from a weakness of the integument—congenital or acquired in consequence of toxic infection The lesions have been observed in areas where there has been an actual shrinking, and have made their appearance at the onset of shrinking She considers them to be a direct consequence of fragmentation of the elastic tissue of the skin attributable to trophic trouble and suggests that as it is reasonable to suppose that this tissue depends for its nutrition on a gland or glands of the endocrine class, the condition may be due to a derangement of endocrine mechanism

321. Pigmentation of the Skin

S BANG (*Ugeskrift for Læger*, July 17th 1924, p 543) suggests that light precipitates as pigment in the skin a substance which if not thus limited to the skin, is capable of being toxic Pigmentation he thinks depends on two factors—a propigment derived from the blood and a ferment in the epithelial cells which converts propigment into pigment He states that this propigment is related to adrenaline, and is similar to or identical with dioxyphenylalanin or dopa. This 'dopa' can be converted into pigment artificially by various oxidizing agents Not only is the chemical formula of 'dopa very similar to that of adrenaline but there are many other points of similarity When the suprarenals are functioning imperfectly increased pigmentation of the skin occurs in those areas where light normally produces pigmentation The author concludes that dopa is a by-product in the secretion of adrenaline by the suprarenals, and that the excessive pigmentation of Addison's disease is due to an overproduction of dopa

Obstetrics and Gynaecology

322. Kielland's Forceps.

G BARBARO (*Gynecol et Obstet* 1924 x 1 p 20) describes and illustrates the obstetric forceps introduced in 1915 by Kielland Many reports more or less laudatory have appeared in German literature but the forceps has scarcely been noticed in English American or French publications He concludes that although the instrument is no ideal nor universally applicable as was claimed it is yet of considerable use in certain cases and deserves systematic trial in countries other than that of its origin The blades of the forceps have almost no pelvic curve and the articulation of the blades is contrived so as to allow a certain freedom of interplay in the longitudinal direction, variation being possible in the height of application to the foetal head The instrument is chiefly intended for high forceps application and is reported to be particularly suitable for seizing the biparietal diameter, whatever its relation to the pelvis may be It is generally conceded that it is admirably adapted for rotating the head, but opinions differ as to its efficacy as a tractor

323 The Dystrophies of Puberty

G BOULANGER PILLET (*Journ de Med et de Chir Prat* September 10th, 1924, p 616) classifies the dystrophies of puberty as those in which changes in the skeleton or stature predominate and those in which the weight increases owing to abnormal obesity In the first group the dystrophy of Hutinel which is more frequent in males is the exaggeration of a normal physiological process the excess or growth affects the lower limbs especially and the extremities are lengthened without showing the thickening which occurs in acromegaly In girls ovarian disturbance is signalled by amenorrhoea oligomenorrhoea or menorrhagia There is a generalized coincident disturbance of other functions with concident disturbance of other functions with muscular insufficiency The dystrophies accompanied by adiposity are more frequent in females in certain cases a transitory dystrophy disappears after puberty but in others the malady increases progressively with advancing age, marriage, pregnancy and lactation The etiology of these conditions is uncertain A morbid condition of the pituitary body has been blamed, little evidence of this however is gained from radiological or ophthalmological or biological tests, and recent work tends to show that the majority of the

so called hypophyseal signs indicate in reality morbid conditions in the tuber cinereum and adjacent regions In several cases the author has found other signs pointing to morbid cerebral conditions—for example, convulsive crises, generally epileptiform, and severe intractable headache Almost constantly he has found that the cerebro spinal fluid shows a meningeal reaction In a certain number of cases signs of syphilis have been present, pointing to a therapeutic possibility which it is important not to neglect It is probable that nerve alterations in the floor of the third ventricle play a prominent etiological part

324 Pregnancy and Acute Appendicitis

A G J HERMANS (*Nederl Tydschr v Geneesk*, August 23rd, 1924, p 1004), who records six personal cases with a review of the literature, states that out of 1,000 operations for appendicitis performed by Kummell, two occurred in the third or fifth month of pregnancy, while among 2,000 cases of appendicitis seen by Sonnenburg three occurred in pregnancy and one in the puerperium Szenes states that, among 325 women operated on at the Zurich Surgical Clinic in the period 1919-21, four, or 1 14 per cent, were pregnant The association of pregnancy and appendicitis is thus a rare condition While some writers, such as Renvall and Fraenkel, regard the occurrence of appendicitis in pregnancy as a mere coincidence, others, such as Sonnenburg, Kalewski, and Pinard, consider that pregnancy predisposes to exacerbations of chronic appendicitis Others again, such as Konig, Boye, and Runge, look upon pregnancy as a safeguard against appendicitis, inasmuch as the hyperaemia of the pelvic organs occurring in pregnancy favours the absorption of the infective material present in the appendix and thus prevents the outbreak of an acute attack Boye reports 12 illustrative cases from Engstrom's clinic in which chronic appendicitis did not relapse during pregnancy The prognosis of appendicitis in pregnancy is generally regarded as very grave Not only is there the possibility of perforation of the appendix and septic peritonitis, but there is a special danger owing to the prospect of abortion or premature delivery and greater likelihood of puerperal sepsis Of 42 cases of appendicitis occurring in all stages of pregnancy reported by Futh, 22 were fatal According to Halban, the mortality from appendicitis, which is usually 12 per cent, ranges from 31 to 59 per cent in pregnancy, and Pribram estimates the mortality from appendix peritonitis in pregnancy at 50 per cent Hermans agrees with De Lee that appendicitis during pregnancy should always indicate immediate operation, and that even in cases of doubt operation is the safer course The earlier the operation is performed the better the prognosis is for the mother and the child In the puerperium the prognosis is graver the earlier the attack occurs after delivery, as the chances of puerperal infection are then greater

325 Pregnancy and Disease of the Heart

S PRASSULIDES (*Arch f. Gynak*, July, 1924) shows that all hearts, whether normal or damaged, increase in size during pregnancy He maintains that in many cases this hypertrophy is desirable, and that, contrary to the general opinion, the occurrence of pregnancy does not damage the prognosis in heart diseases He goes further and states that the appearance of a heart lesion, or even commencing failure of compensation, is not necessarily an indication for interfering with the pregnancy If compensation is established, if the heart muscle is active and undamaged, and more especially if there are no other complications, he believes that there is no danger, either immediate or remote It is only when such complications as recurrent endocarditis, nephritis, or advancing tuberculosis are added to an existing heart lesion that danger occurs Women with heart lesions (of these the worst are mitral) should be kept under medical supervision during the whole of their pregnancy and should never be left to the care of a midwife If the pregnancy is terminated, special attention must be paid to asepsis, in view of the dangers of recurrent endocarditis, thrombosis, and haemorrhage

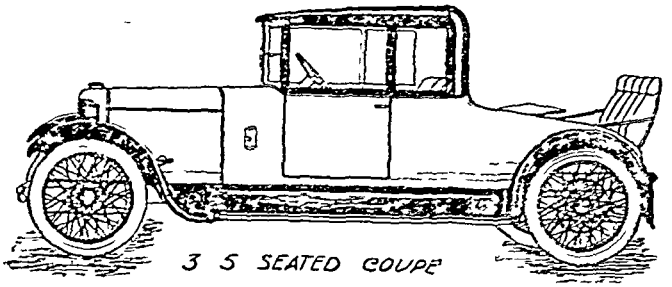
Pathology.

326 A Scarlet Fever Toxin

J D TRASK, jun, and F G BLAKE (*Journ Exper Med*, September, 1924, p 381) show that a toxic substance can be demonstrated in the blood of patients acutely ill with scarlet fever, a similar substance being also found in the urine of a proportion of these patients This investigation was undertaken to provide further evidence in support of the conception that scarlet fever is due to a local infection of the throat by a special type of *Streptococcus haemolyticus*, which is capable of producing a soluble toxic substance, that this toxic substance is absorbed from the throat and causes the general manifestations of the disease, and that immunity, whether natural or acquired, is antitoxic in nature, and can be determined in an individual by finding out whether or not his serum blanches the rash in a patient with scarlet fever The serum of patients acutely ill with scarlet fever was injected intracutaneously into two classes of persons—those whose serum failed to blanch the rash in scarlet fever and those whose serum blanched the rash In the former class a reaction was noted, consisting of a bright red local erythema, varying from 20 to 70 mm in diameter, of one to four days' duration The several reactions were moderately indurated and tender, and were followed by pigmentation and desquamation Control injections in persons whose serums blanched the rash in scarlet fever caused no reaction In one case in which daily investigations were made the toxic substance was found in the blood from the second to the fifth day, and in the urine from the third to the sixth day The toxic substance was not neutralized by mixture with a human serum which gave a negative blanching test, but was readily neutralized by a human serum which gave a positive blanching test It was unaffected by normal horse serum, but was totally neutralized by the scarlatinal antistreptococcic serum of Dochez

327 Carnivorous Diet and Infection with Intestinal Protozoa

R W HEGNER (*Amer Journ Hyg*, July, 1924, p 393) has made a careful study of the literature, and has himself carried out some experimental work on the relationship between a carnivorous diet and the extent of protozoal infections of the intestine Reviewing the literature, he finds that intestinal protozoa in mammals are most abundant in rodents and ungulates, which feed almost exclusively on vegetation, that they occur frequently in those primates which are largely vegetable feeders, but that only on very rare occasions are they found in carnivorous animals He fed three rats for 174 days on a carnivorous diet, all of them were found to be free from *Giardia muris* and *Trichomonas muris*, but two of them had a few specimens of *Hexamitus muris*, control rats from the same colony that had been fed on various diets, largely carbohydrate in nature, were well provided with all three of these flagellates In another experiment 15 rats were fed on a carnivorous diet for one week, and were compared with 15 other rats fed principally on vegetable proteins and carbohydrates It was found that in the former group of animals the numbers of *G muris* decreased to one tenth, and the numbers of *T muris* to one fifty fourth of those present in the latter group Examinations were then made of faecal specimens, at intervals during a period of seventeen days, from 12 carnivorous animals belonging to ten different species which were living in the Zoological Gardens at Baltimore, no protozoa of any kind were discovered except in one instance—that of a wild cat which harboured some giardia cysts He considers that a carnivorous diet is unfavourable for the intestinal protozoa of mammals Possibly this may be due, he thinks, to the putrefactive flora which occurs in the intestine when a carnivorous dietary is being given At present he is working to test the value of a carnivorous diet in cases of human protozoal infection of the intestine



328 The Leucocytes in Various Forms of Arthritis

G KAHLMETER (*Hygiea*, July 31st, 1924, p 449) has investigated the numbers and proportions of the leucocytes in 169 cases of arthritis treated during the past seven years in two Swedish hospitals The cases were classified in five main groups, according as they could be regarded as (1) acute rheumatic fever, (2) primary chronic polyarthritis with fever, (3) secondary chronic polyarthritis, (4) primary chronic polyarthritis without fever, and (5) arthritis deformans The average mean leucocyte count in these five classes diminished uniformly from above downwards it was 9,394 in the first class and 6,036 in the fifth class If a leucocyte count of 6,000 to 7,000 be taken as the normal, the figures obtained by the author suggest that arthritis with fever is generally associated with leucocytosis The differential count showed that the leucocytosis was mainly due to the lymphocytes, in all the classes of chronic polyarthritis there was a certain tendency towards an absolute lymphocytosis, which was least marked in the cases of arthritis deformans The author is of the opinion that there are two main groups of polyarthritis, the disease in one group being due to infections, whereas in the other it is the result of constitutional or endocrine disturbances The first group consists mainly of young persons with anaemia (red cell count below 4 million per c mm), leucocytosis, and fever associated with disturbances in the joints The second group is mainly composed of persons in or beyond the age of the climacteric the polyarthritis is never associated with fever, and their leucocyte count is approximately normal.

De Dion Bouton

The All Enclosed Coupe is entirely new and is a worthy companion of the Doctor's Coupe illustrated. It has two adjustable sliding collapsible front seats which can be so manœuvred to accommodate a stretcher case lying down in case of grave emergency. This design is as practical as it is revolutionary. Two occasional seats disappear in recessed squabs and the continuous boot is five feet long and can accommodate equipment for travelling surgical theatre

Complete Cars from £475

3 5 SEATED COUPE

CLOSED CARS!

THESE significant figures may interest you 20% of last year's De Dion output was purchased by Doctors, 60% of these orders were for the 'Doctor's Coupé', 30% for Saloons and other Closed Carriages, 5% for All-Weather Torpedoes To the long list of Closed Cars specially designed and built for Doctors, there is added a noteworthy Model in the new All-Enclosed Coupé No other Car possesses half the conveniences These figures encourage us to ask for your Commission for 1925, and we promise that for Comfort, Dependability, and Convenience, no other Car will serve you half as well.

MOLOCOLA

Medical and Clinical Experiments have proved that this **GALACTAGOGUE** *is a most efficacious remedy for enabling mothers to suckle their children in cases where it would normally not be possible*

MOLOCOLA is an extract of Hormones of the Placenta of health domestic animals it is consequently effective against Agalactia a malady due to deficiency of hormones in the woman

MOLOCOLA stimulates the activity of the mammary glands throughout the whole period of suckling it ensures a quantity of milk sufficient for the feeding of the baby and exercises a salutary influence upon the health of the mother

The scientific literature on the subject and all desired information are at the service of members of the Medical Profession

THE VIPER CO., LTD., 7 & 8, Poultry, LONDON, E.C.2.

GAMELAN

A product composed of various fatty bodies lipoids and waxy substances It strengthens the lipasic power of the system its saponifying action breaks down the strong resistance of the waxy protective envelope of Koch's bacilli, and diminishes their virulence

Exhaustive experiments made on animals, and clinical researches carried out for a period of several years, have shown that in cases suitable for it the **GAMELAN** treatment *has a favourable and certain effect upon pulmonary tuberculosis and surgical tuberculosis*

The absence of any local or general reaction proves that **GAMELAN** has no injurious effect whatsoever

The scientific literature on the subject and all desired information are at the service of members of the Medical Profession

EPILEPSY

Doctors have proved the value of—

AMBRIODIN

In cases where other treatment has failed It quickly reduces the attacks without the undesirable effects which invariably accompany the administration of Potassium Bromide

A Doctor's Report, states — In the two cases locally the following have been the results A youth of 19 21 who had been under treatment at the local general hospital for many months with little or no benefit Various remedies had been tried by the honorary physicians He was having three or four fits a week I started with one tablet three times daily gradually increasing to two tablets three times daily His fits gradually decreased in frequency and strength and finally when he moved away he was only getting a very mild attack every five or six weeks ' The second case a girl of 17 18 Fits since she was quite young She too had been under treatment at local hospital with same remedies little or no benefit Since she has been taking these tablets her fits are much less frequent and not so strong '

Telegrams BOVMEDICAL, WESTRAND-LONDON *Telephone* GERRARD 3343 (7 Lines).

Established by Bovril, Limited to provide an efficient and reliable transfer service for the Profession at minimum Charges.

Under the personal direction of Dr J. FIELD HALL, and Mr J. C. NEEDES

An Accountant's certified report is required in respect of every practice or partnership the disposal of which is undertaken by the Agency.

The commission charged in respect of any practice in Great Britain placed exclusively in the hands of the Agency for transfer has been fixed on an exceptionally favourable scale the maximum chargeable on any transfer being £50. In the case of Foreign and Colonial practices similarly placed the maximum is £75.

NO CHARGE IS MADE TO PRINCIPALS FOR THE INTRODUCTION OF LOCUM TENENS OR ASSISTANTS.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

PRACTICES AND PARTNERSHIPS FOR SALE.

1. DEATH VACANCY.—HAMPSHIRE.—A very old-established mixed general country PRACTICE, situated within a few miles of a large town. Steady average income of £1,039 including appointments and panel of about 600. Good scope for increase. Advice and medicine, from 2/6. Visits 5 to 20. Midwifery extra. Very little midwifery. House contains lounge hall, dining and drawing rooms, consulting room and dispensary, 5 bedrooms, bathroom, etc. Lit with petrol gas. Garage. Half an acre of garden. Freehold. Price £1,000. Excellent hunting, shooting, fishing, etc. Premium £1,000. Locum in charge.
2. SOUTH COAST WATERING PLACE.—(Population 30,000.)—Partnership with view to succession. A good old established PRACTICE, averaging for the past three years over £1,150 per annum, including panel of over 300. Visits 3, 5 and 7/6. No midwifery. Very nice house available with similar accommodation, garden, etc., which will be sold or can be rented. Half share, freehold, plus a 2 years' purchase. Good society. Sport of all kinds. Educational facilities. Small House. Good scope for increase.
3. PARTNERSHIP.—SOUTH OF ENGLAND.—In a large flourishing Seaport Town a fourth Partner is required in a hitherto mixed-class PRACTICE, averaging about £3,000 per annum, including appointments and panel of nearly 2,000. The sixth share, producing over £800 a year is for disposal. Visits 4 upwards. Midwifery 3 guineas. Commodious rooms at the Surgery are available for the ongoing partner. Rent £60 p.a. Premium required for share 2 years' purchase. Golf, tennis, etc., and there is scope for development.
4. SOUTH MIDLANDS.—In a pleasant Cathedral City a well-established middle and working-class PRACTICE held 11 years by present Incumbent, who is relinquishing, on account of indifferent health. Cash receipts average £1,400 per annum for the past three years, including panel of over 1,100. Visits 5/- and 7/6. Midwifery 3 guineas. Modern Surgery. The house which is Vendor's property, contains 12 rooms, garden, etc., and will be let on lease at £60 a year, or sold for £1,100. Premium £2,100. Excellent educational facilities.
5. MIDLANDS.—In a delightful town (population over 7,000) amidst beautiful surroundings, and within 1 hour's run of London, an old established lucrative PRACTICE worth over £2,500 per annum, including large panel and good fees. The house is well situated and has ample accommodation, and can be rented or leased at £100 a year. Premium 1½ years' purchase. Satisfactory reasons for selling. Educational facilities, and sport of all kinds.
6. [illegible] rooms, standing in its own grounds of [illegible] of an acre, with full size tennis court, etc. Vendor's freehold price £2,300. Good Hospital in town and Vendor on the Staff. Premium £2,700.

[illegible] run of London, established and situated in a very pretty Country Town with beautiful surroundings. Cash receipts for last financial year £2,022, including appointment of £50 and panel of 500. Visits up to 21/- Very little midwifery. Car optional. Railway station. Charming residence (with ample accommodation) in its own grounds of ½ of an acre. Price £2,900 all of which can remain on mortgage at 5 per cent. Premium for practice £2,500. Excellent prospects. Terms. Golf, hunting, shooting, etc.

9. HOME COUNTY.—Hospital Town within 30 miles of London. PARTNERSHIP. A one-half share in a mixed general practice held by seven or eight partners for 25 years. Average income as an Assistant £2,000. Panel of 500. Midwifery and medicine from 2/6. Visits and prices from 3/6. Very little midwifery. Detached Residence, with ample accommodation and good garden. Price £2,000 of which £1,000 can remain on mortgage. There is an open Hospital and an early vacancy on the staff is probable. Good sporting district. Premium 2 years' purchase, half by arrangement.
10. WEST RIDING.—HOSPITAL TOWN within easy reach of University City. Well established middle and working class PRACTICE averaging about £2,000 per annum, existing panel of nearly 1,000 rapidly increasing. Suitable house available. Premium 1 years' purchase, payable £1,800 down and balance by instalments.
11. EAST LIVERPOOL.—In a large town (population nearly 150,000) close to coal mines and within half hour's run of Liverpool, an increasing PRACTICE worth last year £2,100 including 700 panel patients. Visits 2/6 to 5/-. Midwifery 2 or 3 guineas. About 90 cases yearly. Good house with garage and able. Vendor's property and will be let to successful £100 a year, or can be purchased. Premium 1 year's purchase. Every introduction given.
12. NE. COAST.—UPOVTYNE AREA.—Long-established PRACTICE held by Vendor for many years, steadily averaging income of about £3,350. There is a Hospital in the town and a reasonable prospect of obtaining an appointment on the Staff. There are various appointments worth about £150 a year. Very little midwifery but large consulting practice. Fees 4/6 to 21/-. House and Vendor's freehold surgery will be sold. Exceptional facilities offered to a medical man. Premium, for immediate disposal, only £4,000, payable £2,000 down.
13. GROWING COAST TOWN within easy access of London. Old established very sound general PRACTICE. Average income over £1,800. Fees mainly 3/6 to 10/6. Very little midwifery. Very good house, with small garden. There is a Cottage Hospital in the place and the Practitioner offers very good prospects of a Surgery. Premium 1½ years' purchase.
14. FAVOURITE INLAND SPA.—PARTNERSHIP. A well-qualified and experienced man with a good personality is required by a Consulting Physician as Partner with ultimate succession. The present income is only about £1,500 a year but increasing very considerably and the newcomer would be encouraged to undertake general practice with an active aim to the partnership. The fees so obtained. There is a choice of houses both on rental and to buy in the residential part of the town. At present the fees are mainly 1 and 2 guinea but there are a few at 10/6. Premium for the half share £1,500.
15. LONDON NORTH.—Old-established PRACTICE, producing an income of £1,400 a year including appointment worth £220. Panel of 300 in this can be largely increased. Visits and medicine 2/6 to 7/6. Practice easily worked with no conveyance. Fine house in good decorative repair with large garden. Rent £125. Garage can be let. Taxes £23 or £54. Premium £2,000.
16. WEST CENTRAL.—Short easily worked PRACTICE of about £170 a year. This is very good for part even if retired from ill health since the war. Fees mainly 10/6. Very convenient flat. Rent £58. Premium £1,100.
17. FAR EAST.—MEDICAL OFFICER required for railways. Salary about £600 a year, increasing annually. Three years engagement. Free passages and home leave. Age [illegible] English medical qualification. Personal application to Board of Medical Agency.
18. FAR EAST.—ASSISTANTSHIP with view to PARTNERSHIP and immediate occupation for 3 years to an existing practice. Salary £800-£1,000 with [illegible] Knowledge of Tropical Medicine and Surgery essential. Personal application to Board of Medical Agency.
19. FAR EAST.—ASSISTANT required. Minimum age [illegible] years of age and who has seen some service. For 3 years engagement. Salary £630 first [illegible] £70 yearly. Passages and home. Carriage allowance. Good [illegible] social [illegible] terms, good opportunity for [illegible] to be retained.

Profits accruing to Bovril, Limited, from the Agency will be allocated amongst recognized Medical Charities.

Full Schedule of Terms and Conditions will be forwarded on application.

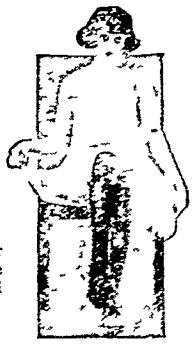
Strong—
yet sterilized 16 times



Sterilization destroys an ordinary Rubber Surgeon's Glove
MADERITE Seamless Rubber Gloves have been sterilized from 16 to 20 times—yet still retain their tensile strength
This is because MADERITE Gloves are made from the heart of para rubber biscuits from the wild rubber trees of Brazil the oldest and strongest rubber in the world
The process of manufacture ensures a glove of even texture and remarkable strength
MADERITE Gloves are available in all sizes rough and smooth and in two varieties

1 " " 1 smooth heavy
2 " " for ortem work

De Dion Bouton

The All Enclosed Coupé is entirely new and is a worthy companion of the Doctor's Coupé illustrated It has two adjustable sliding collapsible front seats, which can be so manœuvred to accommodate a stretcher case lying down, in case of grave emergency! This design is as practical as it is revolutionary Two occasional seats disappear in recessed squabs and the continuous boot is five feet long and can accommodate equipment for a travelling surgical theatre

Complete Cars from £475

3 5 SEATED COUPE

AFTER THE SHOW!

DID you see the new All-Enclosed De Dion Coupé at the Motor Show? Many Doctors did They came to criticise and stayed to admire If you have seen the Show Cars and not yet made your decision let your new Car be a De Dion We know how important it is to you to have dependable service We appreciate that Comfort must be on the highest plane to yield its measure at the end of the long and tiring day And we build accordingly For forty years we have built the ideal Doctor's Car.

The STANDARD WORK on MODERN SURGERY

Choyce's "System of Surgery" is designed for the practitioner of Surgery who desires to keep himself abreast of the most modern teaching, and for the senior student who aims at a sound and comprehensive knowledge of present-day Surgery

This is the only authoritative work on the market which deals in a comprehensive way with modern developments in Surgery and imparts in a lucid and readily grasped form the results of recent experiments and the important knowledge gained as the result of these experiments. The work is in three volumes. Volume I is devoted chiefly to the consideration of Surgical Pathology and General Surgery, whilst Volumes II and III are mainly occupied with a systematic description of the surgical diseases of the various organs and regions by authors whose special knowledge and experience entitle them to write with authority.

A SYSTEM of SURGERY

Edited by C. C. CHOYCE, B.Sc., M.D., F.R.C.S., and J. M. BEATTIE, M.A., M.D., etc.

With Contributions from over 50 Specialists, including all the most eminent Practising Surgeons of the present day

VOLUME I.—SURGICAL BACTERIOLOGY. Introduction—General Morphology and Development of Bacteria—General Biology of Bacteria, etc.—INFLAMMATION. Acute Inflammation—The Cells found in Inflammatory Exudates—Inflammation in Non-Vascular Areas—Inflammation in Lymphoid Tissue, etc.—REPAIR. Essential Processes of Healing—SUPPURATION. Forms—Acute Abscess—Invasion—Outline of the Process—Classification—Disturbances—Innervation—WOUNDS AND WOUND TREATMENT. Wounds—Open Wounds—Surgical Technique—BURNS AND SCALDS. Clinical Features—Death—Pharynx—ONSET—ASSOCIATED WITH TRAUMA. Hæmorrhage—[illegible]—PYREXIA. [illegible]—TUMOUR. Classification—Clinical Examination—Benign Tumour. Lipoma, Fibroma, Myxoma, Glioma, Chondroma, etc. Examination of the Blood and of the Cerebro-spinal Fluid—X Ray Diagnosis—General Anæsthesia—Local Anæsthesia—Spinal Analgesia—Tuberculosis—Acquired Syphilis—Congenital Syphilis—Venereal Diseases other than Syphilis—Yaws—Tropical Sore—Leprosy—Madura Foot—Granuloma of the Pudenda—Glanders—Actinomycosis—Tetanus—Hydrophobia—Anthrax—Surgical Diseases caused by Animal Parasites. Snake Bites, etc.

VOLUME II. THE BREAST. Anatomy—Developmental Abnormalities—Diseases of the Nipple and Areola—Diseases of the Mammary Gland—Tumours of the Breast—THE SPLEEN. Functions—Splenectomy. Rupture. Prolapse. Torsion. Splenomegaly. Abscess. Infarcts. Syphilis. Tumours.—MALFORMATIONS OF THE FACE, LIPS AND PALATE. Development. Macrostoma. Microstoma. Facial Cleft. Fistula of Lip. Mandibular Cleft. Hare Lip. Cleft Palate.—THE TONGUE. Development. General Anatomy. Malformations. Injuries. Inflammation. [illegible]—LIVARY [illegible]—OF THE [illegible]—THE OESOPHAGUS. Anatomy—Methods of Examination—Malformations—Diverticula—Rupture—Injuries—Foreign Bodies—Obstruction—THE STOMACH AND DUODENUM. Anatomy and Physiology—Malformations and Misplacements, etc.—Injuries—Gastric and Duodenal Ulcers—[illegible]—INTESTINES. [illegible]—The Appendix—The Peritoneum—Hernia—The Rectum and Anal Canal—The Liver, Gall Bladder, Bile Passages and Pancreas—The Upper and Lower Urinary Tract—The Male Genital Tract.

VOLUME III.—THE FEMALE GENITAL TRACT. Vulva—Vagina—Uterus—Fallopian Tube—Ovary, etc.—THE CARDIO-VASCULAR SYSTEM. Injuries of the Heart—Contusions and Wounds of Arteries and Veins, etc.—THE LYMPHATIC SYSTEM. Lymphadenitis—Lymphangioma—Lymphatics—Tuberculous Lymphadenitis—Acute Lymphangitis and Lymphadenitis, etc.—THE NECK. Injuries—Cysts. Tumours—Sinuses—Diseases of the Thyroid, Parathyroid and Thymus Glands.—THE NOSE AND ACCESSORY SINUSES. Congenital Malformations—Injuries—Foreign Bodies—Rhinitis—Epistaxis, etc., etc.

AT YOUR DISPOSAL FREE OF CHARGE.

We want you to have the opportunity of seeing this work for yourself and examining it in the quiet of your own surgery. We therefore offer to send it to you for one week's examination free of all charge. Whether at the end of the week you keep it or return it to us rests entirely with your own good judgment. If you do not wish to keep it you can return it to us carriage forward and that will end the matter. If, however, you prefer to keep it, you can pay for it either by small monthly subscriptions or in cash, just as you choose. All you have to do to accept this free offer is to fill up and post the Free Approval Form alongside.

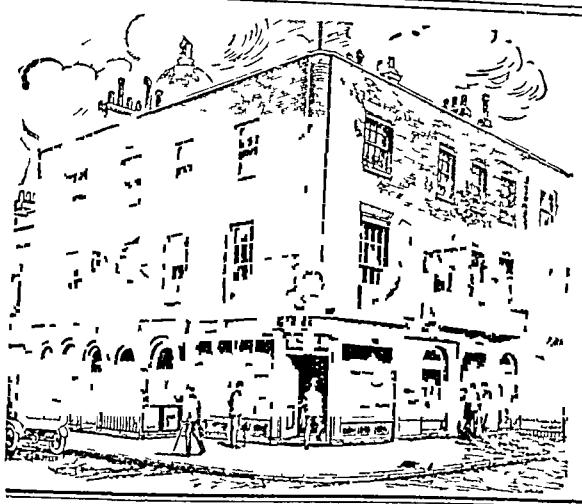
NO CHARGE WHATEVER.

Tear off and Post to-day.

To THE WAVERLEY BOOK CO. LTD.,
96, Farringdon Street, London, E.C.4.

Please send me on approval carriage paid a complete set of A SYSTEM OF SURGERY in three volumes for one week. FREE EXAMINATION without charge or obligation to keep the books. I undertake that I may return them on the eighth day after I receive them and the matter ends.

If I decide to keep the set I agree to send you a payment of 5/- on the eighth day and thereafter four further monthly payments of 5/- each, making the purchase price in all £6.



Price for cash on the eighth day £6

Total Premiums	£38,032	£41,582
LIFE FUND		
New Assurances (net)	£77,950	£137,360
New Annual Premiums (net)	£2,901	£4,446
Total Premiums	£8,461	£12,386
Total Premium Income of the Society	£47,043	£53,969
Total Funds	£368,241	£391,916

The special feature of the Society's Sickness and Accident Contracts is that they are non terminable by the Society, except in the event of a breach of the conditions by the assured, thus securing a permanent income in the event of a prolonged illness

The Society's special Combined Policies, under which Sickness and Accident Insurances, and Endowment Life Assurance can be obtained in a single Policy at less cost than by taking out two separate Policies, are becoming increasingly popular amongst members of the medical profession

These Policies entitle the holder to share in the surplus profits, both of the Sickness Fund and of the Life Fund, and are, therefore, a remarkably good form of investment

Apply for the Society's latest Prospectus "B 4" to the Manager and Secretary

THE HON. BETTY AT TEA

LADY MARGARET A very charming woman I met coming up in the train recommended a Hearing Aid—she said her Doctor had first advised her to use it But I cannot for the life of me remember its *name*

THE HON BETTY I expect it was the AcoustiCON wasn't it?

LADY M Ah! Acousticon —the very name!

HON B It is widely recommended by doctors I know—I believe by all branches of the medical and surgical professions

LADY M How interesting! Have you ever seen one?

HON B Well rather! I'm *wearing* one now! Look. *(Showing the Non Head Attachment)*

LADY M Dear me! Have I been surrounded by them all this time and never noticed one!

Hearing The LATEST WAY

Doctors whether accompanying their patients or otherwise are always very welcome in our Demonstration Rooms where every scrupulous care is always taken in testing and fitting—free and without obligation

THE
New Jaeger Underwear

A Consulting Physician writes —

In my opinion this invention of a Two-layer Stockinet weave constitutes a distinct advance The layers are so ingeniously woven that for all practical purposes the material beha es as a single fabric, whilst the air contained within the meshes acts as a bad conductor of heat renders the garments more hygienic and at the same time lighter in weight than their somewhat *bulky winter weight predecessors.*

In wear the fabric is warm and comfortable and the texture is fine enough not to be irritating

JAEGER

Intestinal Disinfection
No. 9
INTESTINAL DISINFECTION AND THE PREVENTION OF CANCER

ONE of the most noted authorities on Alimentary Toxæmia is firmly convinced of the importance of this condition in the production of cancer

The irritant effects of the stagnating contents of the bowel on the intestinal mucous membrane, accompanied as it often is with ulceration, is obviously a cause of Cancer in the bowel itself According to this writer, the toxins absorbed produce atrophic changes in the breast and other organs which are *specially prone to be followed by Cancer*

There are grounds therefore for hoping that the use of the most efficient of all intestinal disinfectants—KEROL—for prevention and cure of alimentary toxæmia, will do much to PREVENT the occurrence of CANCER

For intestinal d sinfection, use Kerol Capsules (keratin coated) they contain 3 minims of Kerol One to three Capsules may be given three or four times a day after meals

KEROL CAPSULES

Please send for l erature and samples which will be sen free to any member of the Medical Profession

Marmite's Function in the Promotion of Nutrition

MARMITE is a palatable preparation of Yeast and is a food extract that is especially rich in B Vitamin Its effect upon the digestive and assimilatory processes has been amply demonstrated to be beneficial, and in cases of emaciation, loss of weight, and malnutrition Marmite has proved unusually helpful

The presence of a sufficiency of B Vitamin is essential to the proper assimilation of fats, and Marmite supplies this necessary accessory food factor in a very pleasant and easily administered form

Marmite is most palatable and may be recommended as a flavouring for soups, stews, and all meat dishes, and if spread on bread or biscuit it makes an excellent sandwich

Marmite

Medical Practitioners are invited to write for a sample of Marmite, together with full evidence of its usefulness

HALITOSIS

(AS DEFINED IN THE CENTURY DICTIONARY)
(Hal i to-sis) N N L
(L Halitus—Breath Osis—Offensive)

Offensive breath, whether arising from diseased or neglected conditions of the teeth, mouth or nose or caused by disorders of digestion, respiration, the excessive use of tobacco, etc., may be readily overcome by the deodorizing properties of—

LISTERINE

Listerine is strictly antizymotic, it inhibits alike the acid fermentation of carbohydrates and the alkaline putrefactive processes of mixtures of meat and saliva, retained as debris about the teeth, hence, Listerine is antagonistic to the activating enzymes of fermentation so often the cause of Halitosis

The volatile antiseptic constituents of Listerine-thyme, eucalyptus, gaultheria and mentha, combined with baptisia, boric acid, rectified spirits and water have a stimulating effect upon the stomach and in proportion to the dose, an action inhibitive to fermentation of its contents, hence, Listerine is often corrective of those disorders associated with the endo development of gases and acid eructations A large tablespoon of Listerine in a wineglass of hot water will afford immediate relief.

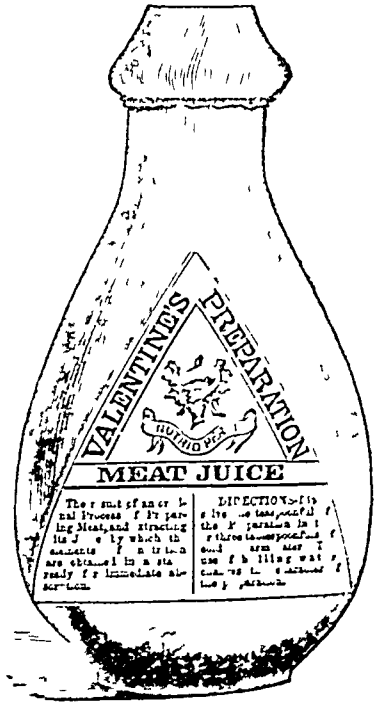
A VALUABLE FOOD BISCUIT

MACFARLANE LANG & CO.'S DINNER TOAST

The DINNER TOAST biscuit, the latest addition to our series of Food Biscuits is composed of the finest wheaten flour, pure butter, malt and milk, contains but a trifling percentage of moisture and makes a crisp, crusty appeal to the palate

Primarily it has been introduced for persons of dyspeptic tendencies who cannot partake of ordinary bread or toast with comfort For such, the DINNER TOAST BISCUIT both from the standpoint of EASE OF DIGESTION AND HIGH CALORIC VALUE, provides an excellent substitute



Taken also with a glass of milk a cup of beef tea or other nutritive fluid the DINNER TOAST biscuit makes a sustaining emergency meal

Half a Tube!

Half a tube of Benger's Peptonising Powders is enough to peptonise a pint of milk, gruel or soup in most cases in 10 minutes. Generally speaking, this is half the quantity required of other preparations whose initial cost is much higher

BENGER'S

PEPTONISING POWDERS

are therefore most economical in use and rapid in result. Professor Stirling says

The great value of such foods has been elucidated by Sir William Roberts while Mr Benger has been able to prepare solutions capable of rapidly producing this result."

Prices No 1—Box of 6, 1/-, No 2—Box of 12, 1/8

An advance in the Science of Nutrition

(2) *The anti-rachitic Vitamin concentrated in GLAX-OVO*

There is in GLAX-OVO a Vitamin Concentrate which no other food contains, the active anti-rachitic principle of Cod Liver Oil, separated as a tasteless and odourless product, and concentrated more than 2,000 times A definite proportion of this active concentrate is present in all GLAX-OVO

In addition to this Vitamin Concentrate GLAX-OVO contains bacterially pure milk, malt extract of high diastatic power and cocoa

GLAX-OVO is claimed to be a valuable source of the anti-rachitic Vitamin, of high nourishing power and of a pleasant fragrance and flavour.

The adequate vitamin content, the high quality of its proteins and its balanced supply of the other food elements, indicate GLAX-OVO for regular inclusion in the normal diet It would appear to be especially beneficial for growing children, and in all cases where there may be Vitamin deficiency

"EVERY DROP SHEER NOURISHMENT"

The Tooth Paste

That millions, the world over, now employ

Pepsodent is now used the world over It is a leading dentifrice in some fifty nations now, and largely by dental advice It is based on three major requirements, urged by modern dental authorities

1—Mildly acid reaction

The acidity combats mucin plaque It increases the salivary flow, and increases its alkaline index as well as its ptyalin index

Investigation shows that peoples who eat much fruit of acid character are notably free from caries Pepsodent is designed to regularly bring the essential effects, such as is produced by acid fruits

2—No soap, no chalk

Soap and chalk mean an alkaline tooth paste They bring the reverse of the Pepsodent effects They reduce the fluidity and flow of the saliva. They reduce its alkaline index, reduce its starch digestant. They weaken Nature's tooth-protecting agents in the mouth

3—Right polishing

The polishing agent in Pepsodent is a blend of finely powdered calcium phosphate and calcium sulphate It is soft mild, harmless, yet efficient. Exhaustive tests have proved it the ideal polishing agent.

Omission of soap—a lubricant—makes this agent somewhat conspicuous But it is far softer than enamel In convincing tests natural teeth have been brushed with it hundreds of thousands of times without sign of ill effect

Ask information

If any questions arise about Pepsodent, ask for information We publish much scientific data Competent men of long experience are here to answer every question

The coupon will bring you a tube for testing

Products of Note

'Alkagen'
TRADE MARK

Tablets and Lozenges

An effective Antacid and Carminative for Hyperacidity and Flatulence Alkagen is an efficient and pleasant preparation possessing the antacid properties of magnesium hydrate with the carminative action of oil of peppermint. It provides a neutralising agent which is easily disintegrated sufficiently soluble and prompt in effect whilst unlike preparations of the alkaline carbonates or bicarbonates it does not cause the evolution of carbon dioxide in the stomach

Alkagen Tablets In bottles of 60 120 250 and 500

Alkagen Lozenges possess an agreeable, mild peppermint flavour they are particularly suitable for the relief of flatulence or the biliousness of children.

Issued in boxes containing 36 and 108 lozenges.

'Cystazol'
TRADE MARK

Tablets

A powerful Urinary Antiseptic. Cystazol is a combination of Hexamine with Sodium Benzoate its action depends on the liberation of formaldehyde from the decomposition of the hexamine that takes place in the urine which has been rendered acid by the sodium benzoate moiety Cystazol is employed with advantage in cystitis bacilluria of all types pellagra gonorrhœa and septic conditions of the urinary tract generally *It is also of special value as a prophylactic* against local infection before and after operations on the genito urinary system

Cystazol is supplied in bottles of 20 40 80 and 160 (10 grain) tablets.

'Alopon'
Trade Mark

Powder, Tablets and 'Azoule' Preparations

A Sedative and Analgesic for general and pre operative use consists of the hydrochlorides of all the alkaloids contained in opium It presents all the therapeutic constituents of opium in a soluble and stable form The mixture of alkaloidal salts whilst exerting a cerebral sedative action practically equal to that of morphine has a less pronounced depressant action on the respiratory centre One grain is equivalent to 5 grains of opium or ½ grain of morphine

In all cases where opium is indicated Alopon may be used with advantage.

"UMBROSE"
Reg. Trade Mark

(Shadow Meal)

For the preparation of test meals used in the X Ray Diagnosis of disorders of the Gastro Intestinal Tract. Umbrose contains 75% of Barium Sulphate and is in the form of an impalpable powder which is treated by a special process in order to secure when administered a clear and regular shadow definition.

Prepared in 3 sizes

Umbrose	No 1	contains 2 oz. $BaSO_4$
Umbrose	No 2	4 oz.
Umbrose	No 3	6 oz.

The Lloyd Roberts Lecture

ON

ATTIC SALT TOR GALL STONES

DELIVERED AT MANCHESTER, OCTOBER, 1924

BY

SIR JOHN BLAND SUTTON P P C S I G,
CONSULTING SURGEON TO THE MIDDLESEX HO PITAL

A CHANCE observation in natural history by a boy may influence him in a particular line of study My father learning that pearls occur in fre hwater mussel led u to collect from the moat a bushel or mu cls, and after carefully searching them he found one pearl as big as a grain of mustard seed This simple experience quickened in me an interest in animal concretions especially pearl I zoars aegagropiles (Fig 1), and finally gall stones The mu eum of the Royal Colle e of Surgeons of England pos e es a large collection of animal concretion which was well displayed and admirably catalogued by Thoma Taylor in 1845 It contains among other things

Gall stones from women men and ap s
Erteroliths from cov and nakes
Vesical stones from cats and dog
And calculi from bovs and h g
Oat hair concretions found in man
Bezoars from wild goat calt and ram
Aegagropiles of many style
From women girls and crocodiles

Bezoars and enteroliths have an interest for mankind Thev form in the alimentary canal of mammals, birds reptiles amphibia and fishes They are common in goats calves and horses especially millers' horses A foreign body such as a chip of wood or metal a button nail or fruit-stone serves as a nucleus and becomes embedded in hairs which mammals lick from their skins and swallow In many instance the foreign body is encased in a deposit of triple phosphates which forms a hard stone-ball TLe deposit is often arranged in concentric layers The example repie-sen-ed in Fig 2 \ is as b g as a cricket ball I have seen one a foot in diameter, and it was used as a door stop in a museum

Bezoar powder is highly prized as a remedy in many countries In the *Dispensatory* of the Royal Colle e of Physicians, 1746, will be found an account of a famous remedy known as 'pulvis e chelis cancrorum compositus' containing tips of crab's claws prepared pearls, and red coral This was converted into "pulvis bezoardicus" by the addition of powder obtained from an Oriental bezoar This mode of prescribing the powder arose from the fact that bezoar powder being costly was sometimes clandestinely omitted In order to heighten the virtue of the powder it was directed to be made into pellets with the jelly of vipers It enjoved great favour for the treatment of epilepsy jaundice melancholy contagious fevers and worms The crab's claws powder was commonly called Gascoign's powder after its inventor

FIG 1.—Aegagropile from the stomach a cow The spiral arrang ment f the hair is due to peri taltic movement (Mu eum Royal Colle ge of Surg on)

FAITH IN DRUGS

Next to belief in the existence of a future place of permanent bliss nothing i more deeply rooted in the mind of man than faith in drugs Among uncivilized tribes the medicine man is of great importance and the filthy things he prescribes are swallowed by members of the tribe with confidence In England in Shakespeare's time many remedies were of the same nature as tho e forming the stock in trade of the African medicine-man Some idea of their nature may be gathered from the list of the ingredients for the hell broth in the famous cauldron scene in *Macbeth* In addition to hemlock root, gall of goat, and slips of yew, it contained

Eye of newt and toe of frog
Wool of bat and tongue of dog
Adder fork and blind-worm sting
Lizard's leg and howlet's wing

The *Pharmacopoeia* of 1746 had little to boast of in comparison with the odd commodities of a witch stew It contained in addition to other curious remedies—

Pulvis e chelis cancer rum compositus
Juxta precepta artis regiae
Chalybis rubiginis pulveriza
Lib sequenti et pulvere varieus

There is great virtue in a Latin prescription It looks like an e orcism (Dean Inge) The above prescriptions smack of dog Latin phraseology and writ in w ten jargon run

Claw of crab and pearls ground in
Viper broth and viper wine
Steel filing and their dried rust
Pills of crap and bezoar dust

In 1900 I was much amused when a distinguished Fel of the Royal College of Physicians recommended me to a man soap pills with the intention' to promote th escape of a gall stone presumably impacted in the common bile duct instead of removing it by operation We laugh at the Chinese vendor of quack remedies who sells at a high price scrapings from the fo silized bones of antediluvian monsters which he calls dragon's bones to be swallowed by rich and poor, forgetful of the fact that three of our most potent remedies are derived from fossilized trees and plants—coal

Some drugs used to-day and professionally sanctioned are remnants of a lingering faith in the medicinal valu of animal secretion and concretion It is true that bezoar powder is no longer prescribed by orthodox physicians but musk, a secretion from the musk deer is recommended as an anti-spasmodic for hysterical maidens Ox-gall as a cure for jaundice still appears in the druggist's list in spite of the inactivity of surgeons in removing obstructions from the common bile duct

PEARLS

The pearl an ornament appreciated in all civilized countries with beauty and riches is formed on the same principle as a bezoar The nucleus may be an intestinal parasite a grain of sand or a small fish entombed in layers of pearl substance—aragonit—arranged around a bezoar (Fig 2 B) The origin of a parasite a foreign nucleus or a particle Raphael Dubois in 1901 to ascribe the pearl as the brilliant secretion of a worm Pearl were formerly used as remedies seed pearl were swallowed while Scrapings from pearls served as ingredients in an electuary prescribed for its stimulant and restorative properties by Arabian physician and the compound powder of crabs claws or the *British Pharmacopoeia* contained prepared pearls and red coral Human credulity in regard to animal concretions has not parallel ambergris a fragrant pathological product found in the guts of sperm whales It was formerly in favour as an aphrodisiac and is still used in the East to flavouring dishes in Italy for piecing wine and in France for scent soap and pomatum

GALL STONES

Gall stones were late in attracting attention from naturalists but also from physicians [illegible] and last of all surgeons The nature of gall stones was ill understood until the French chemist Chevreul recognized the chief constituents of the crystallizable fatty bodies now known as cholesterin Chevreul recognized it as the chief constituent of

stones, and I had the foundation of our knowledge of biliary concretions Gall stones are often formed of spheres arranged concentrically around a nucleus, as in pearls and bezoars (Fig 2, C) The soft brown masses sometimes found in the gall bladder of oxen has been used as drugs by apothecaries and as pigment by artists

Modern surgery is responsible for a great increase in our knowledge of man's viscera This is true of the gall bladder It is established that gall stones are mainly formed in the gall bladder This receptacle is liable to several forms of infection, and the presence of gall stones in the gall bladder and the associated ducts leads to consequences which not only cause discomfort, inconvenience, and pain, but imperil health and life in various ways In 1883 I was busy rearranging the specimens in the museum of the Middlesex Hospital, and became deeply interested in an instructive set of specimens, illustrating diseases of the gall bladder and its ducts, collected by Dr Murchison from the dead-house Murchison held the post of physician and pathologist to the hospital for ten years In 1891 my interest was quickened in the clinical aspect of gall stones, for in that year I successfully excised some gall stones from the common duct of a woman of 58 At that date choledochotomy was a novelty This woman reported herself alive and well ten years later I followed gall-stone surgery keenly, and in 1907 opened a discussion in the Section of Surgery at the meeting of the British Medical Association at Exeter, on cholecystectomy * This formed the basis of my monograph on *Gall-stones and Diseases of the Bile-Ducts* Early in my surgical work I became convinced of the advantage to the patient of removing the gall bladder in preference to draining it, when infected and occupied by concretions, this attitude is supported by recent researches into the mode of formation of gall stones

The study of animal concretions throws some light on the physical and chemical processes concerned in their production Like hailstones, bezoars, and urinary calculi, gall stones are formed around a core, and for a long time it has been accepted by surgeons that this core, or nucleus, may be a clump of shed epithelium, mixed with pigment, crystals of cholesterol, or a cluster of bacteria Infection of the gall bladder is a primary factor in the production of gall stones During the last twenty years investigations relating to this matter conducted by Aschoff, McNee, and Rovsing, indicate that sepsis is not a common cause of gall stones, but sepsis is a serious sequel of gall stones Stasis of the bile in the gall bladder, by permitting the separating out of the constituents from the bile, is also an important factor in the production of these concretions When a gall bladder containing gall stones becomes septic the infection leads to an excess of lime salts in the bile, and these salts coat the stones with mantles of chalk

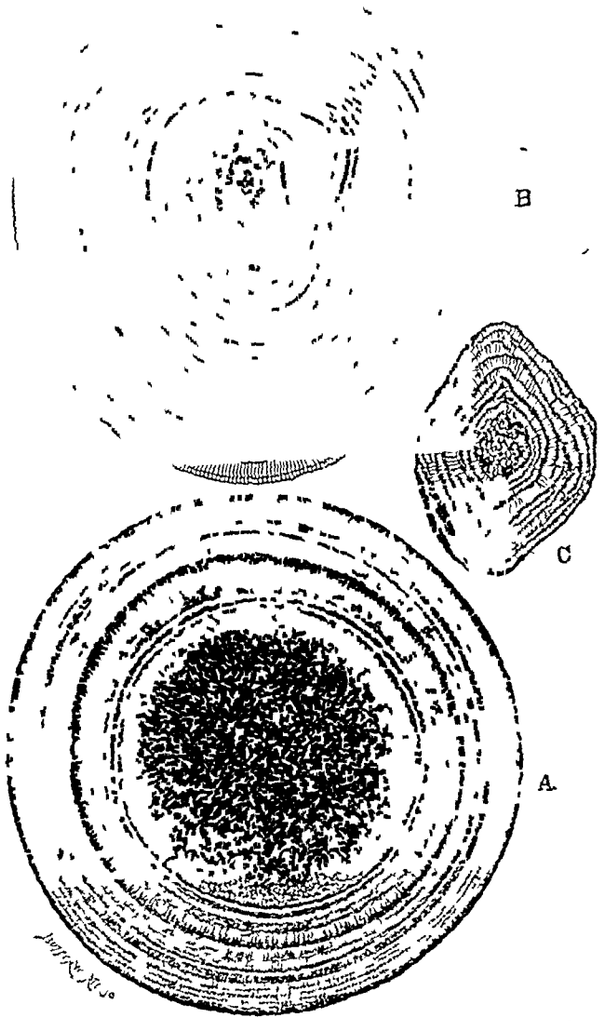

Fig 2—A Bezoar in section The nucleus consists of twigs (Natural size) B Pearl in section magnified (Rubbed) C Gall stone in section It consists mainly of cholesterol (Natural size)

These investigations teach that the majority of gall stones arise in the gall bladder Rovsing believes that the faceted shape of gall stones is not due to the mutual pressure of concretions one upon the other by the spasmodic clutch of the gall bladder He suggests that the facets are the expression of the intrinsic properties of certain gall stones just as in the urinary bladder the oxalate stone is spherical while the urate stone is oval He also suggests that the core of a gall stone is formed of bile pigment Such views destroy the picturesque simile that a gall stone is the tomb of a clump of bacteria In spite of the difference of opinion among men who have studied the modes in which gall stones form, this seems clear temporary bacterial cholecystitis associated with concentration and stagnation of bile is a frequent cause of gall stones The occurrence of chalk in gall stones is of clinical value, it facilitates the detection of stones in the living body by radiology and simplifies diagnosis in an extraordinary fashion

Cholecystotomy

In 1879 Lawson Tait deliberately opened a woman's gall bladder and removed a gall stone impacted in the cystic duct This marked the beginning of gall stone surgery in Great Britain He took no further interest in the extension of this class of surgery and was content with the simple method of cholecystotomy, but this simple experience led his acute mind to realize that the best results of gall-stone surgery were obtained in conditions unassociated with jaundice The removal of the gall bladder seemed to Tait ridiculously absurd, wholly unnecessary, and might have a deleterious influence on the health of the patient

It soon became clear to other surgeons that there were disadvantages connected with cholecystotomy—the mere draining of the gall bladder through an external opening—because the liver excretes 40 ounces of bile in twenty-four hours The bile normally drains into the intestine, the fluid part is absorbed, and the colouring matter mingles with the faeces When bile escapes through a fistula to be collected in a bottle, or caught in cotton-wool or gauze, it is a nuisance In 1894 a medical student submitted to cholecystotomy for calculous obstruction the fistula has been discharging mucus and bile to the present time—thirty years This man clings obstinately to his gall bladder, and has used more than a ton of cotton wool for absorbing the escaping bile

Many surgeons have agreed that when a gall bladder contains an apparently solitary calculus it is sufficient to remove the stone Experience teaches that it is difficult to decide in the course of an operation that the stone is solitary When gall stones exist in hundreds and the gall bladder resembles a bag containing shot, who can be sure that he has emptied it? The sutures used to secure the edges of the opening in the gall bladder to the margin of the incision in the abdominal wall will become encrusted with

* British Medical Journal, 1907, ii, p 577

cholesterol paste and bilirubin calcium, such things are as unpleasant as gall stones These sequelae are well known Experience and observation have taught surgeons that the majority of gall stones are formed in the gall bladder, and it is wise to remove this troublesome pocket when it has acquired the habit of moulding gall stones Surgeons agree in the truth expressed in the epigram "A gall bladder that has been subjected to a cholecystotomy is a liability rather than an asset" In the early years when draining a calculous gall bladder was the rule, surgeons sometimes suggested that recurrence of gall stones was an extremely rare event Few hold this opinion to-day I have removed the gall bladder from many patients who have been submitted to cholecystotomy by various surgeons and found gall stones therein In 1889 Knowsley Thornton removed from the common bile duct of a spinster a large gall stone and one from her gall bladder which was shrunken and useless In 1913 I removed from the ampulla of this woman a gall stone, in shape like a blunt cone, with a vertical height of 3 cm and a circumference at the base of 4 cm (Fig 3) The common duct admitted my forefinger easily

Some of the reasons urged for the retention of the gall bladder are odd A Canadian surgeon stated that an individual with a gall bladder sleeps better than one who has lost it Another reason equally odd, relates to a woman with intestinal obstruction her gall bladder was opened and she was fed for five days through the cholecystotomy opening and finally recovered Once I found the gall bladder useful in a surgical emergency in a man with a perforated duodenal ulcer The tissues around the hole were so rigid that I could not unfold the bowel In this dilemma I plugged the hole with the gall bladder secured it in position with a few stitches and performed a routine gastro-jejunostomy The man recovered in spite of the insult to his gall bladder Hamlet reminds Horatio that the toe of the peasant comes so near the heel of the courtier he galls his kibe Certainly the gall bladder might complain of being put to a base use in these terms

> Although I hold the bile as in a butt
> It is too mean to use me as a bung
> To plug an *opening in a leaking* gut

It is unwise to argue from an isolated experience that a patient should be advised to keep a diseased gall bladder against a similar contingency

CHOLECYSTECTOMY

Reflection on the development of surgery in relation to what is called visceral surgery teaches this—nearly all the methods of dealing with what were called encysted dropsies followed nearly the same order They began with tapping frequently repeated then incision and drainage, the margins of the artificial openings made in the cyst wall being stitched to the edges of the parietal incision Since the discovery of anaesthetics and the use of reliable ligatures complete removal (extirpation) of cysts has been adopted, with comfort and safety to patients Drainage methods were employed for ovarian cysts, hydatid colonies, hydronephrosis, and dropsical distensions of the gall bladder No one uses such methods to-day for ovarian cysts or hydronephrotic kidneys, and they are removed with little risk throughout the civilized world

The operation for removing the gall bladder—cholecystectomy—has passed through a groping stage, then a period of extreme specialization, ending in broad generalization The first time I met Lister in consultation was over a patient with calculous cholecystitis, and I wished to remove the gall bladder Lister agreed with the diagnosis but dissented in regard to operative interference, for these reasons When the abdomen is opened and nothing big removed it is very difficult to secure the abdominal wound safely He explained to me that his own experience in this matter had been very sad I am old enough to have seen the evil results when abdominal incisions failed to unite by primary union, and it is a privilege to have lived to see Listerian principles of wound treatment universally accepted and abdominal incisions heal as readily as surgical incisions of the face and limbs.

For twenty years I have consistently followed the practice of removing the gall bladder when occupied by gall stones, pus or infected bile Many surgeons only remove it when cholecystotomy is impracticable, and many hesitate to remove it in the condition known as acute septic cholecystitis The best results follow cholecystectomy for septic cholecystitis

Tanner (1924) analysed 117 consecutive cases of gall stones, operated on in Guy's Hospital and found that patients submitted to cholecystectomy were fairly as long in the hospital as those submitted to cholecystotomy The advantages of cholecystectomy are even more striking when the patients themselves are seen" in preference to trusting reports

An important fact in regard to diseases of the gall bladder revealed by modern surgery concerns cancer of this receptacle Thirty years ago primary cancer of the gall bladder was regarded as a rare disease few specimens were available for study, and all of them in pathological museums, were spoils from the dead house To-day primary cancer of the gall bladder is known to be a frequent disease and rebellious to surgical treatment, it is often found in gall bladders excised for gall stones, and its presence unsuspected until the parts are examined in the laboratory Gradually it has been established that in 95 per cent of cancerous gall bladders, gall stones are also present It is a fact that gall bladders submitted to cholecystotomy for gall stones and drained temporarily, or permanently are liable to become cancerous This is a strong reason for removing the gall bladder when patients suffer from calculous cholecystitis

VAGARIES OF THE GALL BLADDER

Some of the abnormal relations of gall bladders give rise to clinical puzzles The fundus of a gall bladder has been found strangulated in the sac of a right femoral hernia (Museum, St Bartholomew's Hospital) In a sexagenarian spinster under my observation the gall bladder containing many calculi could be easily felt through the thin abdominal wall and the gall stones made to grate together in the course of a clinical examination A gall bladder may be so mobile that it rotates and twists its narrow neck like a rope In size a gall bladder with its cystic duct obstructed with a calculus may become so distended with mucus as to reach the pelvis and resemble in clinical characters an ovarian cyst Lawson Tait began an operation under the impression that he was dealing with an ovarian cyst his astonishment was great when he discovered it to be a gall bladder converted into a huge mucocele The cystic duct was obstructed by a solitary gall stone and the gall bladder contained eleven pints of fluid Distended gall bladders of twice and thrice this capacity have been reported by Collinson and Terrier A similar experience occurred in my practice I expected to find a large subserous cystic fibroid but found a huge calculous and cancerous gall bladder in contact with the fundus of the uterus

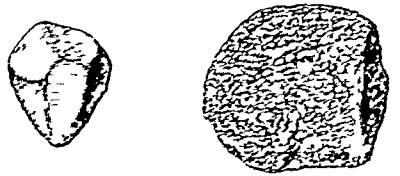

FIG 3.—Two gall stones (natural size) The larger was removed from the common bile duct of a pioneer The faceted stone was removed from the ampulla of a spinster aged 70 who had had no signs of jaundice A calculus excised between the gall bladder and colon (Museum St Bartholomew's Hospital)

When the gall bladder is converted into a mucocele with thin translucent wall its removal is a simple surgical exercise When it resembles a big red sausage with thick walls and as tense as the parchment of a well tuned drum, it startles the novice in surgery In such a case until stripping of the gall bladder from its bed in the liver is easily accomplished and with little bleeding because the hepatic vessels in immediate relation with the gall bladder are bound however the eyes of the patient may be in such condition it bleeds viciously and may delude the surgeon into the idea

that he has cut the hepatic artery It is worth remembering that the surface of the liver, stripped by the removal of a simple mucocele, will often bleed more freely than after the removal of an infected gall bladder When the detachment exposes a wide area of the liver, bile sometimes leaks from small bile ducts thus damaged, sometimes so freely for twenty-four hours or more as to raise the suspicion that the ligature has slipped off the cystic duct

Complications of Cholecystectomy

An important complication of calculous cholecystitis is fistulous union of the gall bladder and colon due to ulceration and escape of gall stones into the gut A gall stone which slips into the colon in this way may be as big as a bantam's egg The museum of St Mary's Hospital, London, contains a segment of pelvic colon with a gall stone of this size impacted in it, and with fatal consequences Many stones escape through fistulous openings in the gastro-intestinal tract, to the permanent advantage of the patient The orifice of escape in such a complication shrinks to a narrow funnel and thus occasionally resembles a cord In dealing with apparently solid cords a ligature should carefully be applied, a narrow channel communicating with the gut may exist in it and be sufficient to set up local sepsis, illustrating the maxim—a small leak neglected may sink a great ship

Nothing seems more surely established in clinical observation than the idea that complete obstruction of the common bile duct is inevitably followed by jaundice A spinster, aged 50, complained of a pain in the region of the gall bladder She was thin and I could feel a gall stone in the position of the common bile duct There was neither sign nor history of jaundice I removed a large stone from the common duct which had completely plugged it (Fig 3) The gall bladder adhered to and communicated freely with the transverse colon In this woman the bile found its way to the gall bladder by the cystic duct and dribbled through the fistula into the gut, to the patient's temporary advantage As the removal of the stone reopened the natural outlet for the bile, I removed the gall bladder and closed the hole in the colon The woman reported herself in good condition ten years afterwards

The gall bladder is a diverticulum of the hepatic duct The mere loss of the gall bladder is unattended with sinister consequences Many mammals and birds lack a gall bladder Some parrots have a gall bladder and some not Hamlet, in his soliloquy on the First Player, says

> But I am pigeon-liver'd and lack gall
> To make oppression bitter
> *Act II Sc 2 605*

This clearly indicates Shakespeare knew that the pigeon lacks a gall bladder Absence of the gall bladder neither causes inconvenience nor shortens life In 1906 I removed the gall bladder of a widow, aged 76, for acute calculous cholecystitis The mucous membrane of the gall bladder was thickly beset with flakes of cholesterol and glistened like the tinselled coat of Harlequin The patient lives, aged 94, and bids fair to become a centenarian

Radiography and Gall Stones

One of the difficulties in persuading patients to submit to operative treatment for suspected gall stones was uncertainty of diagnosis 'Give us a sign" was the imperative and persistent demand Many *physicians preferred to trust* soap pills and olive oil, *rather than the scalpel* The position has changed Radiography can secure shadows on photographic plates which indicate not only the presence of gall stones, but their size and shape *With such evidence* patients now willingly submit to surgery, and, as a rule, quick healing, *freedom from* leakage, and from the recurrence *of gall stones*, with quick restoration to health and usefulness, are the usual consequences of cholecystectomy *To operate for acute cholecystitis and not remove the gall bladder is as reprehensible as operating for gangrenous appendicitis and leaving the appendix*

The golden rule for surgeons to observe is this Examine the main ducts—cystic, common, and hepatic—especially the ampulla, and be satisfied they are free of concretions, remembering always *An undiscovered concretion in the common duct will wreck a cholecystectomy* The imminent tion may be long delayed *but it will surely come* Although the medicine-man can point to some wonderful cures and sorcerers can eject *out imaginary devils*, neither a sorcerer nor a physician can expel gall stones

LUMBO-SACRAL BACKACHE

BY

P JLNNER VERRALL, F R C S,

ORTHOPAEDIC SURGEON, MINISTRY OF PENSIONS HOSPITAL, SHEPHERD'S BUSH AND NORTH-WEST HOSPITAL FOR CHILDREN
CHIEF ASSISTANT ORTHOPAEDIC DEPARTMENT, ST BARTHOLOMEW'S HOSPITAL

Lumbo-sacral *pain is exceedingly common*, very disabling, and often so resistant to treatment that patients will resign themselves to it Either its treatment devolves *on the* general practitioner entirely, or the patients, if they can afford it, go from specialist to specialist in search of relief We have often to deal with a vicious circle involving many systems, but with only one symptom—pain This pain may be situated in various positions, may or may not be affected by turning of the spine, standing, or walking, and may be variously described as sharp, *gnawing*, or aching It is of the first importance in diagnosis *to obtain* an accurate account of this symptom *from the patient* We may simplify the subject *by dividing the possible causes* into five groups, three of which, the most serious, will not detain us long, but must be carefully excluded *before we consider the other more common causes* We have to deal with a *complex system of bones*, joints ligaments, muscles, and nerves, but we may separate the sacro-iliac joints for consideration later

Severe Bone and Joint Disease

Caries of the lumbar spine is not uncommon, and it must be remembered that adults are by no means exempt and that caries does not necessarily affect the bodies of the vertebrae, but may affect, though less commonly, the laminae, transverse processes, etc Diagnosis will be made by consideration of the extreme rigidity, possible deformity and abscess formation, and by the *x-ray* findings Spinal skiagraphy is by no means easy, and in doubtful cases it is essential to have a skiagram by an expert expertly interpreted The possibility of gummatous deposits *in the spine* must not be forgotten, the symptoms resemble *those of tuberculous caries*, and the two diseases may coexist Syphilis of the spine is, however, a rarity, and the same may be said of sarcoma, *but secondary carcinoma*, frequently associated *with a mammary tumour* (possibly unsuspected), is by no means *uncommon* Forewarned is forearmed, and severe localized pain *coming on in a patient liable to* carcinoma will lead to an adequate *x-ray examination*, when diagnosis is usually easy, as the skiagraphic appearances are generally characteristic Aneurysm and acute osteomyelitis are of course, exceedingly rare, but we must not forget them I do not propose to enter into the treatment of these cases as this would take us too far

Arthritis of the Lumbar Spine

Here again the skiagram affords us the *only absolutely* sure method of diagnosis Lipping of the edge *of the* vertebral bodies and osteophytic outgrowths are characteristic These latter may even go to the extent of complete fusion, producing actual bony ankylosis between the vertebrae Severe arthritis (spondylitis *deformans*) with its fixed absolutely rigid spine, is fortunately rare, as treatment can achieve little more than the arrest of the disease when it is well advanced *early diagnosis being the only hope* Gonorrhoea is *responsible for* at least 65 per cent of such cases Some surgeons would put the percentage higher, but quite 30 per cent are due to metastatic infection from

* Delivered before the War Section on April 1st

the intestinal tract (dysentery, typhoid, and even *Bacillus coli*), and this quite apart from the acute or subacute spondylitis not uncommon during the later stages of such diseases, and of less serious prognosis if correctly treated Spondylitis of this type is often associated with iritis both in the gonococcic variety and in the intestinal, the infective agent in the latter is either the primary organism or, more commonly, a streptococcus which has reached the system through the open intestinal ulcers Rarely, perhaps in 5 per cent, spondylitis deformans is due to metastases from other septic foci Milder degrees of arthritis of metastatic origin are common Moderate rigidity and pain in the lumbar spine combined with intermittent attacks of lumbago are associated with such arthritis It must not be assumed that every case of lumbago has arthritis, as the affection may be a pure fibrositis, but arthritis is sufficiently frequent to justify a skiagram, which will often reveal either slight lipping of the vertebral bodies or quite as commonly osteophytic outgrowth in some of the interneural joints

Treatment will follow the usual lines as for arthritis elsewhere In the acute stage rest is imperative, either on a frame or plaster bed in severe cases, or in mild cases simply in bed with the lumbar spine supported by a pillow Where abnormal curves are in course of development an attempt should be made to correct these by suitable padding of the bed or frame during the period of recumbency It would be absurd to condemn every patient suffering from slight spinal arthritis to permanent spinal fixation Radiant heat, counter-irritation, and ionization may suffice for mild cases Subacute cases may need firm fixation in a plaster jacket for a time but in chronic cases where the disease is sufficiently extensive to justify fixation the ordinary Thomas's back brace will meet all requirements and patients will be so much relieved by wearing it that they will not complain of the necessary fixation of the spine While carrying out this local treatment a rigorous search must be made for the toxic cause bacterial or chemical, and the appropriate treatment applied

Traumatic

Arthritis is often of traumatic origin a relatively mild trauma providing a point of diminished resistance to the attack of the circulating toxin as so frequently occurs in the joints of the extremities But we may have more severe lesions A history of violence, direct or indirect, will lead to the necessary investigation There may be lesions of bone ligaments, or muscles, or all together, or simply a concussion

Of the grosser lesions crush fractures of the vertebral bodies are commoner than is usually thought and we must not be blinded to the possibility of their occurrence by a history of comparatively slight immediate disability after the accident, as the fracture is impacted and there is relatively little instability If undiagnosed, such fractures will often yield gradually to the body weight and a deformity will appear with the necessary concomitant symptoms of spinal distortion In young subjects considerable violence is necessary, and the war provided us with many examples in men who had been blown up and buried under heavy masses of earth, and such accidents occur also in civil life In older patients however far less violence is needed I have a patient a lady of 65 who sustained a severe crush fracture of her first lumbar vertebra by stumbling when getting out of bed and falling with her back across a chair Minor fractures of laminae and articular processes arise not infrequently from indirect or direct violence, often during athletic pursuits Diagnosis is all important, and the skiagram should ensure this when there is any doubt

Treatment in the initial stages is by rest and complete fixation of the spine, and the prognosis is good firm union usually occurring in three or four months Subsequent symptoms will be due either to vertebral distortion if such has been allowed to occur, or to adhesions either in the joints themselves or round the exits of the spinal nerves Such adhesions are not always preventable, but much may be done by instituting exercises at the correct moment It is not easy to judge this moment accurately, but symptoms and the skiagram will, with experience be sufficient guide In old standing cases, where the skiagram shows firm union, it is quite correct treatment to break down adhesions by mobilization and to follow this up with active exercises

Spondylolisthesis must be mentioned, but is very rare It may occur either gradually or by sudden violence The skiagram of such a case shows a dislocation of the lumbar spine on the sacrum, causing a noticeable hollow in the back above the sacrum The skiagraphic appearance in this case is unmistakable, the antero-posterior view showing the round outline of the vertebral body, and the lateral view (if obtainable) the dislocation forwards Apart from the well known obstetrical considerations, such cases if they have symptoms or a progressive deformity, must be treated with a firm back brace with adequate abdominal support

Sprains of the spine are common, especially in those engaged in athletics Obviously many structures are involved together, and a more or less accurate diagnosis is obtainable only by a study of the symptoms produced by movement in various directions It is hardly necessary to add that such movements must be made with extreme care owing to the pain caused and to the possibility of the injury being more severe than one had imagined A skiagram should always be taken if circumstances permit Treatment consists in rest at first, and fixation either by strapping in mild cases or by plaster in severe ones When the acute symptoms have passed off local massage will aid absorption or effusion and expedite repair, and graduated active exercises should be instituted at the earliest date consistent with safety This latter is essential if adhesions are to be prevented, but in practice is very difficult to control, and it may well happen that adhesions form, and there may be pressure round the exits of spinal nerves with resultant neuralgia Fortunately we can easily recover the lost ground, when all acute symptoms are passed, by mobilization of the spine followed by exercises

Mobilization to be effective must be thorough, and the method described by Sir Robert Jones[1] represents the usual practice of orthopaedic surgeons Nitrous oxide anaesthesia is sufficient for the mobilization of the minor joints but it does not provide adequate relaxation for the treatment of the shoulder, hip or spine A full anaesthetic is given and the knees and hips fully flexed so as to get control of the pelvis Then while an assistant steadies the shoulders, the pelvis is held and the spinal movements of flexion, extension, lateral flexion, and rotation are performed seriatim to the full degree Mobilization must always be followed by active supervised exercises, commencing on the day following the operation

I have said that trauma may cause concussion without an organic lesion I refer to the familiar railway spine of the textbooks The spine may be held absolutely rigid and the symptoms may be pronounced, but moments of relaxation by subterfuge may often be obtained Characteristic spots of tenderness to pressure will usually be found on either side of the spine opposite the exits of the spinal nerves, the patient will be evidently neurasthenic and inclined to exaggerate symptoms and finally the skiagram will be negative I do not wish to dwell long on this subject suffice it to say that, when the legal aspect of the matter has been settled, mobilization will have both a moral and physical effect especially if combined with the application of a cautery (or even simply a scrubbing brush) to the back, and an assurance of cure Akin to this is the hysterical spine characterized by the same tender spots and often a fantastic attitude I will not presume to encroach on the domain of psychological medicine except to remind you that such cases often do this in mimicry of a genuinely diseased acquaintance Will they be treated by the orthopaedic surgeon or by the psychologist suggestion is the clue to treatment The surgeon will combine this with mobilization and the psychologist with actual hypnotism

Mechanical

We now come to the commoner and more important cause The back is an exceedingly complex structure containing a large number of bones joints, ligaments, and muscles whose functions are interdependent,

First, what are the potential movements of the spine? *Flexion and extension* occur mainly in the lumbar spine[1] and are those movements which mainly concern us at present Side bending is mainly lumbar in the erect position In flexion it occurs rather higher and in hyperextension lower Side bending and rotation are largely combined, rotation, however, being more a dorsal function It is well to remember that in the flexed spine the dorsal bodies rotate to the convex side of the curve and in the extended spine the lumbar bodies rotate to the concave side, the result being that dorsal rotation is greater and lumbar rotation less than an examination of the spinous processes would lead us to suspect One must also bear in mind the normal curves of the spine and their method of development The primitive foetal type is an antero-posterior continuous C curve The cervical lordosis commences to form soon after birth and the lumbar at about 6 months, the former being complete at about 1 year, and the latter developing more gradually The maintenance of these acquired curves depends on muscular action, and any lack of muscular tone leads to a tendency to reversion to the foetal type with associated pain, from dragging on ligaments, etc , and from the efforts made to prevent this reversion This naturally brings us to a consideration of the effect of the muscles in maintaining position The erect posture is maintained by balance combined with the integrity of the postural contraction of the essential muscles For a thorough understanding of this postural contraction we are indebted to the researches of Sherrington and to the application of his results to orthopaedic subjects admirably set forth by Bankart[2] To summarize his conclusions briefly The contraction of muscles is of two kinds—phasic, concerned with movement, and postural with the maintenance of posture Those muscles which normally serve to maintain the erect attitude are capable of either of these two functions, and there is reason to believe that the two functions are controlled by separate innervations, that of postural contraction passing through the sympathetic chain

In normal postural contraction no fatigue is caused, and the muscle has the peculiarly convenient quality of being capable of adapting itself to different lengths without change of tension Ultimate control comes from the paracerebellar nuclei, which are in intimate connexion with the higher centres and with the semicircular canals

Although we have seen that fatigue does not normally occur, very slight causes suffice to upset this balance and voluntary muscular action must be called to assist Neurasthenia, adenoids, eyestrain, and excessive mental work are merely some of the causes of this You are all familiar with the child who is devoted to books, works hard at homework, and generally gets prizes, but who complains of backache and has a hypholordosis *No exercises will cure* such a child, the muscles are not weak, but their control is insufficient and we must treat the cause Bankart has made the important observation that in such cases the myasthenic reaction is present, which is conclusive proof of the truth of the above What is true of such a child is true also in older people, and a search for a cause of lack of nerve control, toxic or mechanical, will frequently enable us to cure an obstinate backache We must also remember that in the aged there is normally an obliteration of the acquired curves and a reversion to foetal type, combined with decreased postural activity from general weakness

The immediate effect of such lack of adequately balanced muscular control is that the spine is left unsupported, and open to the influence of outside factors Habitual posture alone will not influence the spine, but when resistance to distortion is absent it will do so The result may be a scoliosis, quite pliable and easily corrected in the early stages Diagnosis is easy, inspection of the back will reveal the curve Pain will be chiefly complained of on the convex side owing to excessive strain on ligaments and to increased voluntary muscular effort and consequent fatigue There is frequently an actual acute lumbo-sacral angle which produces a concentration of pain in the lumbo sacral region This angle is usually obvious, but a skiagram will detect it with greater certainty The importance of its recognition lies in the necessity for correcting it before correction of the superincumbent spine is attempted On the other hand, the spine may yield in an *antero-posterior* direction and cause pain

No description of these defects would be complete without reference to Goldthwait's types[3] This very careful and accurate American observer has described two types of *person* particularly liable to suffer from lumbo sacral backache, and most people will agree with him His first type, termed by him the visceroptotic, has a long narrow back, flexible spine, and increased lordosis, with a sharp angle at the lumbo-sacral junction The effect of this is obviously to produce an increased strain at the sacro-iliac joints, and pain is located there His second type is the reverse of this—a thick-set body with slight lordosis and little movement of the lumbar spine Here the strain is thrown on the lumbo-sacral angle

The abdomen of a quadruped is supported directly from the vertebral column by muscles aided by a certain amount of elastic tissue The adoption of the erect attitude in man has necessitated a different mechanism, and a lordosis is developed This serves to balance the body, and at the same time to afford some support to the liver *Nature* also anticipates intermittent increases in weight in the human abdomen The most important of these is that of the gravid uterus, but food in the intestine and increased adipose tissue on the abdominal wall are also provided for Pregnancy is a normal function, and the various necessary *alterations are so marvellously successful that we should* expect no ill effects The savage woman develops increased lordosis and carries on her normal work *without* complaint, modern civilized woman develops the lordosis, but her overstrained nervous system refuses the postural contraction of the erector spinae, and she must use voluntary effort with consequent fatigue and pain at the lower attachment of the erector spinae The wearing of a pregnancy belt is the price she pays for civilization Pregnancy is, after all, a normal function, but overloaded intestines and an abdominal fat pad are not Actual enteroptosis may be added to this, and the resulting disturbance of the centre of gravity is great At the same time there is no natural tendency to compensate for this by increased muscle power and tone in the back, on the contrary, there will be toxicity and weakness At first voluntary effort will be required, with consequent muscle strain, effort, and fatigue When this fails all the strain will be thrown on the ligaments, with resulting pain from this cause This is perhaps the commonest cause of lumbo-sacral backache, the pain being felt mainly over the lumbo-sacral attachment of the erector spinae On the other hand, we may find a diminished lordosis with pain due to perpetual ligamentous strain without adequate muscular support In those women who are compelled by their social status to undertake heavy domestic duties a common cause of backache is to be found in the *low wash-tub and low kitchen sink Perpetual* stooping over these when tired throws an impossible strain on the erector spinae, lordosis diminishes, and backache is constant The remedy is obvious At the other end of the social scale, modern fashion has decreed that women shall have no hips, a flat back, no mammary development, and a head bent forward In scientific language we may describe this as a deliberate reversion to the foetal type of spine with obliteration of the normally acquired curve As modern life must of necessity throw a large strain on the nervous system of such women, we cannot expect a great degree of postural activity in their muscles The result is inevitable When once voluntary action becomes fatigued pain must and does follow, while the necessary subsequent redevelopment of the normal curves is naturally associated with additional pain from ligamentous strain Against the dictates of fashion the doctor is powerless, but he can do his duty and advise, and even if his advice be neglected for the moment it may be appreciated later on

Abnormal spinal curves may be due also to outside mechanical causes A large number of people have one leg shorter than the other The vast majority of these develop no deformity and no symptoms, but a pelvic tilt must exist, and where symptoms do occur we must notice and correct it by a high boot Increased lordosis may be associated with genu valgum and *flat foot in which there is* internal rotation at the hip and a consequently inclined pelvis

Similarly in talipes equinus there is pelvic tilting from insufficiency of the posterior structures of the leg Such deformities will need appropriate correction

Sacro iliac Joints

In England sacro iliac disability is considered rare but in America considerable attention is paid to these joints, and I think, rightly The characteristic symptoms are first, pain at the site of the joint, increased by any jar on the limb of the affected side, such as stepping off a step, and a feeling of insecurity, which is easily understood when we remember that the whole weight of the body above this point must be transmitted through these joints Examination will reveal deep tenderness over the joint (to be distinguished from the superficial tenderness due to referred pain) and pain elicited by lateral compression of the pelvic crests These signs and symptoms are common in greater or lesser degree to all sacro-iliac troubles Examination by *x* rays is of doubtful value, as, although gross disease such as tubercle will be readily shown, milder arthritis and relaxation cannot be diagnosed by this means, as no accurate joint line is obtainable in the skiagram owing to the tortuosity of the joint In tuberculosis, a very serious disease, symptoms will be marked possibly there will be intra or extra pelvic abscess formation and we shall be unlucky if we fail to see evidence in the skiagram Metastatic arthritis comparable to similar diseases elsewhere is by no means uncommon and is a source of severe backache, but perhaps the commonest trouble in these joints is relaxation of the ligaments Jones and Lovett[1] say that such relaxation is uncommon and they have rarely seen it With all possible deference to such high authority, I think it is quite common The outstanding cause for this is childbirth In ruminants these joints are normally relaxed to such an extent before labour that the cowherd can foretell the approximate date of calving from palpation of them After birth involution takes place in them *pari passu* with that of the uterus Precisely the same phenomenon occurs in women—with this difference, relaxation is less marked, but woman is a biped and her sacro-iliac joints must stand a relatively greater strain than do those of a quadruped In such cases there is a tendency for the sacrum to fall forwards and downwards producing a painful tension on the ligaments Here prevention by adequate rest after labour is better than cure, but in old standing cases rest will do much and should be insisted upon, *treatment being continued by means of a pelvic brace or* better one of those close fitting elastic corsets reaching well down on the hips that for some reason or other the Parisians are more expert at making than others

Tuberculosis is fortunately rare, but is of grave prognosis Definite tubercle will need years of recumbency and fixation although operation by bone graft has in recent years much improved the prognosis and shortened the period of treatment Grafting of this joint, as usually practised, is a difficult operation, consisting in the placing of a graft across the affected joint Frequently in doing this an abscess is opened, and although this is not a contraindication to the operation it is certainly a complication Acting on the suggestion of my assistant, Mr Fleming recently in cases both of tubercle and of simple metastatic arthritis I have adopted the plan of placing a long bone graft from the tibia through both posterior superior spines of the ilium, the graft resting on a prepared bed in the sacrum under the erector spinae muscles Such a graft is easily *inserted requires no additional fixation, and to my mind* represents a sound mechanical principle—that of the tie-beam Weight is transmitted downwards along the vertebral column and is resolved to a certain extent laterally through the sacro iliacs, the graft having therefore the same effect as do those iron bars with X-shaped pieces at the end that are customarily seen on houses which have become insecure This procedure will shorten the period of treatment *in tuberculous cases, and in others severe enough* to need operation causes relief as soon as the graft has united, and (so patients tell me) prevents that feeling of insecurity which is so terrible and which is the cause of the neurasthenia so commonly associated with sacro-iliac weakness

Sacralization of the Fifth Lumbar Vertebra

We are again indebted to America for observation of this defect High authorities[1] tell us that, although it occurs, it is rarely responsible for symptom With this I agree but when it does cause symptoms they are very severe In a certain number of individuals the fifth lumbar vertebra is fused to the sacrum, giving four lumbar and six sacral vertebrae This in itself does no harm, and is found out by *accident in a skiagram* In some cases however (sometimes combined with fusion of the bodies and sometimes without), the transverse processes of the fifth lumbar vertebra take on sacral characters and impinge on the ilium, forming a joint The condition may be very painful it can be diagnosed only by *x* rays, and a good stereoscopic skiagram is necessary before we can pronounce it certainly present It may cause no symptoms at all, but if symptoms occur they consist in intractable pain both local and referred to the area supplied by the fourth lumbar nerve, as the junction between the fourth and fifth lumbar nerves lies immediately anterior to the process Treatment consists in removal of the process, and the proximity of the nerve junction and the depth of wound necessary if the *process* is approached directly from the back render the operation difficult It is far better to approach the process by cutting a window from the iliac crest opposite it, as this serves the double purpose of removing the impinging process *and the structure on which it impinges* and is incidentally a relatively easy operation We will not delay longer with this moderately rare condition it will suffice if we realize the possibility of its occurrence

Referred Pain

I have already referred to the sympathetic system, and we have seen that it is probably the channel of control of the postural activity of the skeletal muscles Sherrington maintains that the tone of hollow viscera controlled by the sympathetic, is in reality postural activity In addition nutrition is controlled through the vasomotor fibres of the sympathetic But the sympathetic contains also the sensory *nerves of the viscera* The ganglia ted cord is connected with the spinal nerves by white rami communicantes, which arise from the anterior primary divisions from the second dorsal to the second lumbar nerves and from the third (sometimes second or fourth) sacral These rami obtain from the ventral root motor and secretory fibres and from *the dorsal root the sensory nerves for the viscera* These fibres are said to occur not only in the white rami, but to be capable of reaching the sympathetic chain by way of the grey rami By these grey rami the axons of sympathetic cells reach each of the spinal nerves and it is by them that postural and vasomotor control of the body is maintained For the purpose of this lecture the upper part of the sympathetic does not concern us

It is clear that as the sensory nerves to the viscera are the axons of spinal ganglion cells pain derived from the viscera may be referred to the somatic area served by the same ganglia and it is often so Study of cases combined with a consideration of anatomy will often enable us to diagnose the source of trouble A few examples will suffice to illustrate this

The lesser splanchnic nerve from the ninth and tenth dorsal ganglia reaches the solar plexus and thence through the superior mesenteric plexus reaches the intestine as far as the caecum Pain from this origin may be felt in the lower dorsal and upper lumbar region down over the crest of the ilium and in front The least splanchnic nerve from the last dorsal ganglion reaches the renal plexus and pain from the kidney may follow the distribution of the twelfth dorsal nerve Fibres from the first two lumbar nerves pass by the aortic and inferior mesenteric plexuses to the colon, and an overloaded colon in addition to the backache etc, may cause by its mechanical weight and by the toxins it may cause to enter the circulation may also cause backache (both lumbar and in the buttocks) by pain referred along the distribution of these two nerves

In the sacral region referred pain is common The upper sacral nerves communicate directly with the pelvic plexus, and pain is referred from the uterus bladder prostate etc

This pain is commonly felt over the sacro-iliac joints, but I would again emphasize that it is not a deep pain, and a little practice will easily enable us to discriminate between this and the deep tenderness associated with pain on lateral compression of the pelvis which is characteristic of sacro-iliac disabilities. It would seem that by calling attention to such a multiplicity of possible causes of lumbo-sacral backache I have but added to the difficulties of the subject, but these cases are very trying and often the trouble is of very long duration. By realizing the possible causes we may often by systematic examination and exclusion reach the correct solution at once, or, even if we do not do so, we may appreciate the fact that the pain is due to several of these causes combined in a vicious circle, and we may attack the different parts of that circle seriatim and achieve a cure.

To summarize briefly: in examining a case of lumbo sacral backache first exclude gross disease, injury, and arthritis, and have a skiagram taken. Then look for outside mechanical causes and outside causes of overstrain of the nervous system. Finally, remember the paramount importance of the sympathetic system and seek for referred pain.

Treatment has been briefly indicated in each case, but the value of mobilization in suitable cases must be remembered, and this valuable therapeutic measure should not be relegated to outsiders.

ACUTE DIABETES FOLLOWING MUMPS

BY

ADAM PATRICK, M.D., M.R.C.P.,

PROFESSOR OF MEDICINE, UNIVERSITY OF ST. ANDREWS; VISITING PHYSICIAN, DUNDEE ROYAL INFIRMARY

THE occurrence of pancreatitis as a complication in the course of an attack of mumps is well known, and has frequently been described. Farnam[1] in 1922 collected 119 such cases from the literature, and added one of her own, in which laparotomy was performed. She summarizes the case records thus:

> An acute abdominal condition, probably pancreatitis, is sometimes associated with epidemic parotitis. It occurs more often in boys and young men than in other classes of the population. It usually follows, but may precede, the parotitis or may be the only manifestation of the disease. It is characterized by intense epigastric pain often vomiting, occasionally diarrhœa or constipation, and a slight rise in temperature. A mass may sometimes be felt in the epigastrium. It usually runs a short benign course and has not been known to affect the internal secretion of the pancreas.

All these 119 patients, with one exception, recovered. It may be stated that the only cases in which the pancreas has actually been seen at this stage are Farnam's (at operation) and Lemoine and Lapasset's[2] (*post mortem*). In the former case the pancreas was found to be red and tense, with three probable areas of fat necrosis, and the impression gained was one of acute pancreatitis.

Lemoine and Lapasset's case was that of an Algerian soldier who was admitted to hospital with mumps on October 2nd, 1902. The attack was at first simple but on the tenth day there occurred shivering, with high fever, and swelling of the testicle. By the fourteenth day the temperature had fallen to normal and the patient seemed to be well enough for discharge from hospital. Next day, however, he complained of having slept badly, and had vomited. The temperature was normal but there was epigastric tenderness and the spleen was palpable. Jaundice and more vomiting followed, and he died on October 18th, after an attack of hæmatemesis. At the *post mortem* examination the gall bladder was found to be swollen and œdematous, apparently from pressure by an enlarged gland on the common duct. The pancreas had almost tripled its normal weight (190 grams), and was œdematous and congested with swelling of the lymph glands round about. Histological examination showed a general increase in size of the islets and epithelial cells with diminution in size of the islets of Langerhans, through pressure of the swollen ducts.

Although symptoms of pancreatitis are thus relatively common in the course of mumps, glycosuria or diabetes has seldom been described, and Garrod[3] in his Lettsomian lectures (1912) commented on the rarity of glycosuria in this connexion. I have been able to find records of only three cases in the literature, with a doubtful fourth, and I add a brief description of a fifth case, a very acute one, which recently came under my own observation.

1. Harris[4] (1899) describes the case of a farmer, aged 42, who three years previously had had an attack of mumps. A month after recovery from this attack polyuria had set in, thirst, hunger and loss of weight followed, and these symptoms had continued with gradually increasing severity. When Harris saw him he was emaciated, having lost 50 lb. in weight, and the knee-jerks were absent. 6,440 c.cm. of urine, containing 4·6 per cent. of glucose, were passed in the day.

2. Barbieri[5] (1903) mentions the case of a boy, aged 6, who contracted mumps during an epidemic. Six days after the onset of the symptoms he complained of continuous pain above the umbilicus which radiated round the right side to the right lumbar region. The pain was attributed by the parents to worms, and the child was dosed with calomel and santonin. The abdominal pain continued, and next day there were also vomiting and diarrhœa. After two days of this the boy developed a voracious appetite and great thirst, but everything he ate was vomited an hour later. He drank 2 litres of water in a day. Barbieri was now called to see the patient, and found that he had slight epigastric tenderness, while the fæces under the microscope showed many droplets of fat. The urine had a specific gravity of 1034 and contained sugar. 2,400 c.cm. were passed in twenty-four hours. The symptoms subsided gradually, and after fifteen days had disappeared. By that time the urine was sugar-free, the specific gravity being 1015 and the daily amount no more than 600 c.cm.

3. Gillespy and Holden[6] (1917) record the case of a lad aged 16, who in May, 1916, had an attack of mumps without testicular or abdominal symptoms. On the third or fourth day of this illness the patient became very thirsty, and began to pass a large quantity of urine. When seen in hospital he showed pronounced signs of diabetes mellitus with sugar and acetone bodies in the urine. Tuberculosis of the lungs also was present, and he died in five months. The authors mention that at the *post mortem* examination some islets in the tail of the pancreas were found to show hyaline degeneration.

4. The case which I have classed as doubtful was described by Routh[7] in 1912. Here a man, aged 58, on April 13th developed a right-sided parotid swelling, which was attributed to a chill experienced five days before. Two superficial ulcers were present on the right side of the tongue. Some pyrexia followed and extension of the swelling to the submaxillary region. By April 28th the swelling was more severe, and incision under an anæsthetic was contemplated. On examination the urine was found to contain sugar and aceto-acetic acid (specific gravity 1038). By May 1st the aceto-acetic acid had disappeared, and on May 2nd the urine was free from sugar. This case would seem not to have been one of mumps, but rather one in which glycosuria was associated with septic parotitis.

I shall now describe a case in which diabetes followed mumps and ran a rapid course to death, the patient coming under my care in the last stage.

5. E. A., a girl aged 8, was admitted to Dundee Royal Infirmary on December 2nd, 1923, in coma. The history was that five weeks previously she had developed mumps which ran an ordinary course, and in which there had been no complaint of abdominal pain. Two weeks after the attack of mumps came on she began to pass a large quantity of urine and had to get up sometimes twice in the course of a night to empty the bladder. She complained of great thirst and her appetite increased. After a week the polyuria lessened but the other symptoms continued unabated. There was also pronounced constipation. A few days before her admission to hospital she became confused mentally, and on November 30th she failed to recognize her friends. She went into coma on December 1st, and when brought to hospital on December 2nd was deeply unconscious. A specimen of urine obtained by catheterization showed 8 per cent. of glucose and much aceto-acetic acid, and the breath had a strong smell of acetone. In spite of treatment by insulin she died within thirty-six hours, without recovering consciousness.

It is interesting to note that although abdominal pain is present in the common type of pancreatitis which complicates mumps, it was absent in Gillespy and Holden's case, and, as will be described, and it is not referred to as having occurred in Harris's, the only three cases of mumps among those recorded in which true diabetes seems to have developed.

A CASE OF HAEMATOPORPHYRIA CONGENITA (CONGENITAL PORPHYRINURIA)

BY

HUGH T ASHBY, B A, M D CAMB, I R C P,

VISITING PHYSICIAN TO THE ROYAL MANCHESTER CHILDREN'S HOSPITAL ETC

THE child to be described first came under notice at the age of 12 months, and the reason for the child being sent to the hospital was the dark red colour of the teeth The case was then thoroughly investigated, and proved to be an example of haematoporphyria congenita Very few of the cases have as yet been recognized and recorded so early in life Sir A E Garrod and Mackey[1] report one similar case and I am indebted to the former's book, *Inborn Errors of Metabolism*, for help

The child was apparently born healthy and had had no illness of note She had been easy to bring up All her life however and even directly after birth she had passed urine which was red in colour and stained the napkins red The teeth were cut at the usual time and were dark red in colour The parents took her away to the seaside at the age of 4 months the weather was then very hot and sunny She came out in a rash on the face and back of the hands which the mother described as looking like chicken pox

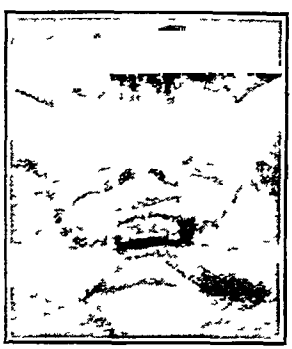

FIG 1.—Showing the pigmentation (red) of the milk teeth

Condition on Admission

The child aged 2½ years is well grown and apparently healthy She has been under observation for a year and a half and the urine has been of the characteristic port wine or red colour every time it has been examined It contains no albumin or blood corpuscle I am much indebted to Dr A Sellars for the spectroscopical examination of the urine and faeces For this purpose the acid extract from the urine and the alkaline extract from the faeces were used

Spectroscopic Examination — Acid Extract Position of two bands mean central position at 6 200 and 5 640 (Angstrom units) *Alkaline Extract* Position of four bands at 6 480 6 200 5 640 5 280 (Angstrom units) The position of the bands was ascertained by plotting against the spectral lines of lithium sodium thallium and strontium

The blood shows no abnormal condition and there is no enlargement of the spleen A most striking feature of the case is the marked red pigmentation of the milk teeth She cut her first tooth soon after the age of 6 months and it came through red in colour Dr Wigoder ground a tooth and the colour was as deep as the tooth could be ground showing that the pigmentation is not superficial only The child was demonstrated at a meeting of the British Dental Association and no one had seen or heard of a similar case It will be interesting to examine the milk teeth further when they are shed and also to see the condition of the permanent teeth Only very rarely has the pigmentation of the teeth been noted Curiously enough the bones *do not* show pigmentation when transilluminated by an electric bulb nor do they show any changes on x-ray examination The fundi of the eyes also show no abnormal pigmentation

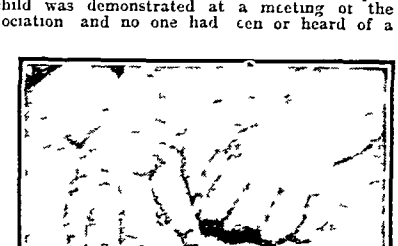

FIG 2.—Hydroa vacciniforme showing the large bullae some of which have burst

The child was again taken to the seaside this year during a spell of hot weather and had to be brought home again on account of large blisters appearing on the face back of the hands and front of the knees This condition is called hydroa vacciniforme Her face had become markedly pigmented from the sun and there were large bullae on the affected parts The blisters some of which had burst contained clear fluid of a reddish colour Scarring has been left after the blisters have healed The hair and the clothes give complete protection The nails of the hands were also affected and had become dark red as if they had all received a blow causing bruising It is certain that great care will have to be taken in the future against exposure to the sun to prevent serious disfigurement

Sir A E Garrod concludes that the outlook for these cases is serious and that there is a liability to tuberculosis This patient is, however, in good health and as long as precaution against excessive sunlight is taken, there is at present no sign that the child should not grow up and remain well The family history of the child is negative Most cases of porphyrinuria are the result of taking sulphonal or an allied drug for a considerable period

The cause of the condition is unknown, but it is probable that the porphyrin is an intermediate product in the conversion of haemoglobin into bilirubin as suggested by Hans Fisher Whatever the exact cause may be it is an inborn error of metabolism

Haematoporphyrin is a most remarkable sensitizer A small quantity of this injected into white guinea-pigs renders them so sensitive that they die from exposure to light Meyer Betz made himself very ill by exposure to very moderate light, after injection of a very small quantity in order himself and remained hypersensitive for weeks

FATAL CASE OF ANEURYSM OF THE SPLENIC ARTERY

BY

DUNCAN C L FITZWILLIAMS C M G, M D, CH M F P C S

IT is well recognized that aneurysms are the risk of the strenuous life led by men and are uncommon in women they are to be expected at that time in life when the tissues are beginning to weaken but the vital forces and feelings which impel violent action still remain at their height They can be caused directly or indirectly by trauma which weakens the vessel wall, while certain diseases by sapping the strength of the vessel wall, predispose the individual to the condition Among the commonest of these diseases are atheroma and syphilis, while a less known cause is tubercle A nodule of tubercle settling in the vessel wall may quite well be the cause of an aneurysm in those positions where a compensating fibrosis is unable to reinforce the strength of the vessel For this reason aneurysms are sometimes met with in the brains of children—one such case is within my own recollection There is also a case in which an important verdict depended on the result of the *post-mortem* examination, where a man had been seen to strike a boy upon the head and the boy shortly afterwards died it was supposed from the blow Examination showed that a tuberculous aneurysm had ruptured in the ventricles of his brain

These being the well recognized factors in the production of aneurysms when we find that all these are set aside and we meet with an aneurysm in a woman of the age of 27 engaged in a light occupation without any other sign of disease, and the aneurysm is not single but one of three it seems to be a case that is worth recording more especially as the symptoms resembled those of a ruptured gastric ulcer or an ectopic pregnancy in many of their features

The case was as follows

Jean O C aged 27 single employed as kitchenmaid at a good address in London was admitted to St Mary's Hospital Paddington on November 27th 1923 at 4 p.m

History.—Sudden intense pain had come on with great tenderness in the pit of the stomach at 2 p m soon after food with nothing whatever to account for it and she was sent in by her doctor as probably a ruptured gastric ulcer

On admission the patient was in a state of extreme collapse from shock she was pale cold and clammy and in great pain On inquiry she had never had any indigestion pointing to a gastric or duodenal ulcer Her blanched condition made one look for symptoms pointing to an ectopic pregnancy but there was nothing to indicate this Light touch over the abdomen was not painful but any pressure caused great pain Her condition was very doubtful and it was decided to leave her for some two hours to see if the shock would pass off The respirations were 30 temperature 98° and pulse 120

At the end of one and half hours the hands were better but the symptoms pointed still more strongly to haemorrhage and it was still more blanched and her pulse weaker and rapid and she was inclined to be restless

At 6 30 operation was decided upon as I out any definite diagnosis being made She was opened above the umbilicus when the

abdominal cavity was found full of blood A dresser at once prepared and gave her intravenous saline Blaming myself for believing a single woman's history about her menstrual periods, and thinking that it was obviously a case of ectopic pregnancy, an incision was rapidly made above the pubes, only to expose a perfectly normal set of pelvic organs On mopping out the blood and clots the whole of the peritoneum of the posterior abdominal wall was found to be one huge tense haematoma, almost filling the abdominal cavity and approaching the anterior abdominal wall Blood had found its way into the mesentery of the small intestine and to a certain extent into the omentum The lesser sac was full of blood, and was emptied in the hope of finding the main bleeding point, but the whole area seemed to ooze blood and no bleeding vessel was seen As the patient was in a critical state and nothing was to be gained by prolonging the operation, the abdominal cavity was filled with saline solution and the wound closed He was sent back to bed, and the foot of the bed raised She died at 10 30 that night

At the *post mortem* examination the splenic artery was found tortuous and there were three aneurysmal dilatations along its course The largest of these was the size of a walnut, and situated near the hilum of the spleen It had calcified walls, which showed that it was not of recent formation This had ruptured and was the cause of the bleeding into the tissues behind the peritoneum The aorta and the arteries appeared healthy and there was no sign of the origin of the condition

British Medical Association.

PROCEEDINGS OF SECTIONS AT THE ANNUAL MEETING, BRADFORD, 1924

SECTION OF LARYNGOLOGY AND OTOLOGY.

W Jobson Horne, M D , President

PRESIDENT S OPENING REMARKS

The President, in opening the proceedings of the Section, said that, while he had no intention of inflicting a presidential address upon the Section, he could not refrain from expressing his appreciation of the honour conferred upon him The officers of the Section, after fully considering the choice of several subjects suggested for general discussion, had unanimously decided upon the two subjects now submitted—namely, "Chronic tonsillitis indications for treatment and results obtained," and "The importance of early treatment of acute otitis" The officers, in making this selection, were fully alive to the fact that the subjects were time-worn, but it was felt that there were points which would bear repeating if not emphasizing, and, moreover, that the matters to be discussed were of daily occurrence, and therefore of more practical value than other subjects less commonplace but more academic Dr Jobson Horne reminded them that the Section met on two days only, but it was his hope, with the help and support of the large number present, to get three days' work into two days

DISCUSSION ON CHRONIC TONSILLITIS INDICATIONS FOR AND RESULT OF TREATMENT

OPENING PAPERS

I —A BROWN KELLY, M D , F R F P S ,
Surgeon for Diseases of Throat and Nose, Victoria Infirmary, Glasgow

The term "chronic tonsillitis" designates a long-continued, mild inflammation of the tonsil, oftener, however, it is used to imply a state of the tonsil which is not manifestly inflammatory but which predisposes to acute attacks The two conditions of the tonsil which are mainly accountable for chronic inflammation and recurrent exacerbations are hypertrophy and sepsis, these are commonly associated

In discussing the indications for treatment of chronic tonsillitis, we have to deal, not only with the disease itself, but also with its distant effects, further, in making choice of a method of treatment it may be necessary to take into account special circumstances—for example, the patient's age, general health, or occupation

The commonest affection of the tonsils with which we have to deal is that of enlargement in the young This may give rise to various symptoms which experience has taught will pass off when the tonsils are removed, consequently we advise operation, and in the great majority of cases our recommendation is accepted or even welcomed by the parents, the benefit generally obtained being a matter of common knowledge On the other hand, various objections to operation may be advanced on the patient's behalf or may arise in our minds First among these is the natural disinclination to the removal of an organ or tissue not obviously diseased It should be remembered, however, that an enlarged tonsil, although apparently healthy on probing, squeezing etc , if examined microscopically after enucleation will be found to be diseased According to Dietrich,[1] the tonsils, even in earliest childhood, are attacked by acute inflammatory changes of all degrees, without signs or symptoms, in the course of various diseases of the upper air passages (measles, bronchopneumonia, etc) Similarly, Howarth and Glover[2] found evidence of bacterial infection in every tonsil examined, these cases ranging from 2 to 15 years of age while D J Davis doubts the existence of a normal tonsil after the first few days of life From the bacteriological standpoint every tonsil is therefore a diseased tonsil It is obvious that we cannot utilize this criterion, so that it becomes necessary to base our opinion mainly on the clinical history, concomitant signs, and local aspect

Another question which occasionally perturbs patient and doctor alike, especially since tonsillectomy has become *de rigueur*, is whether this operation may not abrogate or destroy some important function from the deprivation of which the patient will suffer This is conceivable in the young child and will be referred to immediately, but our everyday experience proves the contrary, so that we may cease to be discomposed by physiological misgivings For the present it should suffice to remember that the tonsil is made up of numerous nodules of lymphadenoid tissue precisely similar to those found, not only in the pharyngeal and lingual tonsils, but also scattered singly or in small groups beneath the mucous membrane of the pharynx, and that the faucial tonsil differs in no way from any solitary nodule excepting in that it consists of an immense collection of such nodules Schlemmer[3] has recently emphasized these facts, and maintains that there is no anatomical or physiological reason for assigning the tonsil a separate position or special function

If, then, the tonsillar function is shared by the lymphadenoid tissue throughout the pharynx and naso-pharynx, is it not probable that when the tonsil is removed its functions are carried on vicariously by the lymphadenoid tissue elsewhere? For, as already stated, no deleterious effect on the constitution has been traced to the mere absence of the tonsils after operation This view gains support from a sequence of events occasionally noted In a young child with large adenoids and small tonsils, if the former are removed and the latter left, it is not distant date the tonsils are found to have enlarged considerably, moreover, in children whose tonsils and adenoids are completely removed large granulations sometimes appear on the posterior or lateral wall of the pharynx and become inflamed from time to time

In very young subjects the age is often advanced as a contraindication There need, however, be no hesitation in removing enlarged or diseased tonsils from a child of 2 years, or even of 18 months, if healthy and vigorous When younger, in order to lessen the bleeding and shock it is advisable to operate on the adenoids first, and after an interval of weeks or months to deal with the tonsils It may be imperative to remove adenoids from a sucklin but it is rarely necessary to operate on tonsils before the completion of the first year of life

Does the removal of tonsils increase or diminish the susceptibility to contagious diseases? In young children when the tonsils are at the height of their physiological

activity two of the functions assigned them by certain investigators are protection against bacterial invasion by phagocytic action, and immunity resulting from the production within the tonsil of self immunizing agents. Removal of the tonsils in childhood would demand even more consideration than it receives if these opinions were established, but as yet they are largely hypothetical. According to the view generally held enucleation lessens the liability to contagious diseases, and when such diseases are contracted the attacks are milder in those who have undergone operation. Place's[4] observations add support to this opinion. He states that in scarlet fever in tonsillectomized cases the throat symptoms are slight. In a few cases under his observation in which only one tonsil had been previously removed the tonsillectomized side of the throat was nearly normal, while the tonsillar side showed the usual picture of scarlet fever. Severe faucial diphtheria is excessively rare in those who have had the tonsils removed. In his experience there has been little if any indication of a deficiency in the resistance of tonsillectomized cases. Zahorsky, on the contrary, thinks it probable that an attack of acute tonsillitis renders the patient temporarily immune to a variety of dangerous infections and that the child beginning his school life without the tonsils is in greater danger of acute diseases than one who still has them. As Logan Turner[5] states: "The answer to the question, 'Are the tonsils a protection or a menace?' must be in the affirmative as regards both counts." In short, we should determine whether the tonsils are clinically healthy or diseased and act accordingly, but in the young they should not be removed as a matter of routine procedure.

The question of the role played by the tonsil in producing enlargement of the cervical glands frequently arises. The tonsil, although not obviously diseased, is likely to be the etiological factor if the tonsillar gland is involved or if the glandular enlargement is preceded or accompanied by tonsillar pain or swelling. In such circumstances, and when the tonsil is enlarged or septic, its enucleation should be carried out. Howarth[6] has shown that the enlargement of cervical glands is not necessarily tuberculous, but in many cases is simple and due to chronic irritation. He thinks that this stage often precedes a tuberculous invasion, as was pointed out by J. H. Nicoll many years ago. Howarth considers that the tonsil is the portal of entry, and holds that the most important factor in the treatment of chronic glandular enlargement is the elimination of all primary foci of infection—the removal of the tonsil rather than of the cervical glands. In a large percentage of patients this is followed by the subsidence of the glands and possibly after a year or even longer, by their final disappearance. It is advisable in such cases to mention beforehand the possibility of the operation lighting up the inflammation in the gland and leading to its suppuration.

Singers, professional voice users, and the parents of children whose voices give special promise often inquire whether the removal of the tonsils is not liable to damage the voice. A great deal has been written and said to prove the groundlessness of this fear. The latest contribution to the question is by Vorhees,[8] who bases his conclusions on evidence adduced by physicians and singing teachers from 5,000 operations. The consensus of opinion shows that in the hands of skilled operators there need be no fear of damage to the singing voice that bad results are most often due to cicatricial contractions from careless dissections and that the good results likely to follow far outweigh any other consideration. In spite of this reassuring pronouncement caution is called for. If the operation is done before puberty nothing but benefit is likely to result; later in life however when the vocal training is completed surgical interference should be undertaken only after careful circumspection. The removal of a deeply seated septic tonsil cannot readily harm the voice but enucleation of a large tonsil over which the anterior pillar is stretched in a patient who has been singing for years may interfere with the adjustment of the pharynx, predispose to vocal fatigue, and impair the quality of the voice. In such subjects therefore if operation is necessary, gradual reduction is to be recommended—for example, by morcellement, diascission, the galvanocautery, or London paste (Irwin Moore). When the mere size of the tonsil is causing trouble contraction by radium might be considered.

In adults with chronic tonsillitis the disturbances due to sepsis are commoner and more important than those from hypertrophy. The sepsis may be manifest, as in the chronic lacunar variety. The tendency for tonsils on which tonsillotomy has been performed to become thus affected, and the local and constitutional benefit following the enucleation of such stumps have long been recognized. It is of the latter variety of tonsillar sepsis however, that I desire to speak. In recent years the subject of focal infections has received a large amount of attention in every branch of medicine. In view of the frequency with which the tonsil is the seat of a septic focus it behoves us to contribute what we can towards the elucidation of this difficult problem. I understand that it was largely with this end in view that chronic tonsillitis was chosen as the subject of to-day's discussion.

The faucial tonsils are peculiarly adapted for the development of septic foci. They are furnished with long, narrow, tortuous, branching crypts reaching to the capsule which favour the retention and accumulation of lymphocytes, leucocytes, and epithelial debris. The resulting collection may be considerable and as no secretion is poured into the crypts whereby they are flushed out the contents in this protected situation serve as an ideal breeding ground for micro-organisms, so that septic changes readily take place. The blood vessels and lymph channels running in the trabeculae and passing through the capsule establish the connexion with the general circulation and thus allow of metastatic infections.

The opinions which have been expressed as to the influences governing the localization of infections are still *sub judice*. Until comparatively lately a secondary focus was believed to develop at a particular site in consequence of previous injury of the tissue involved whereby its resistance was lowered. In many cases this explanation holds good and has been confirmed experimentally. The present tendency however is to adopt Poenow's[9] view and to assign to the circulating virus the power of selecting a certain tissue for its lodgement and growth. According to the same authority the organisms are supposed to acquire their different degrees of virulence and their different affinities for various structures in the primary focus of infection. Another factor which in some cases may play an important part is the invasion of the cells of a tissue by bacteria from a septic focus in the tonsil so that the cells are sensitized and react to minute doses of a homologous virus.

The detection of a septic focus, or good grounds for suspecting the presence of such, in a tonsil is manifestly a matter of importance. The presence of foul caseous plugs in the crypts or enlargement of the tonsillar gland may facilitate the diagnosis. In many cases however it is difficult or impossible by mere inspection to say whether a tonsil is healthy or diseased. The absence of signs by no means excludes the presence of a small chronic abscess close to the capsule or of a collection of decomposing debris at the bottom of a long crypt. It is often under such conditions when retention is more or less complete the affection latent and the tonsil apparently innocent, that most injury is being caused. In this connexion some useful deductions can be drawn from what has been learned with the help of radiology regarding dental sepsis. Thus Bertram Watson[10] believes that too much stress has been placed on pyorrhoea as a causative factor in the production of systemic disease and that it is of secondary importance to apical infection in which the deeply seated toxic process may be unaccompanied by suppuration.

Various procedures have been recommended and slightly described to aid the diagnosis of focal suppuration in the tonsil. French[11] introduced a tonsillo-scope for transillumination of the suspected structure but I am not aware of this ingenious instrument having been extensively used. Paterson-Smith[1] considers that redness limited to the tonsil and its immediate surroundings and especially a vertical red streak about an eighth of an inch wide running the whole length of the anterior pillar is a sign of chronic tonsillar infection. General redness of the fauces and pharynx he regards as more suggestive of oral or nasal infection. Quite recently Lott[12] has described and

NEW EDITION. SQUIRE'S

PHARMACOPÆIAS of the LONDON HOSPITALS.

NINTH EDITION *Published by J. & A. CHURCHILL, 7, Great Marlborough St., London, W.1*

Foolscap 8vo. Pp. 451. Price 12s. 6d. per copy. Postage 6d.

A systematic comparison of the formulæ of thirty-one of the London hospitals including the Children's Hospital and the French Hospital. The formulæ are arranged under the headings of the various preparations so that an immediate comparison may be made between the practice of the different institutions.

The British Medical Journal says — "The value of the book to the medical profession is even greater than that of its predecessors, and it comprises a practical compendium of all the latest medical treatment."

The Lancet says — "There can be no question of the practical utility of a book which presents an exhaustive comparison of the pharmacy of the London hospitals; for in the clinic institutions the formulæ will be selected for the best reasons, which the knowledge of the day can furnish, by their elected representative leading authorities on all therapeutic questions."

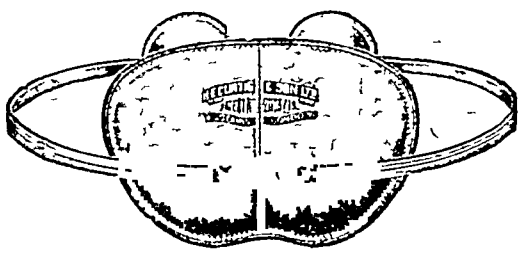
New Edition **PRINCIPLES OF GENERAL PHYSIOLOGY** *Just Published*

By Sir W. M. BAYLISS, M.A., D.Sc., LL.D., F.R.S., late Professor of General Physiology in University College, London.
Fourth Edition. With Illustrations. 8vo. 28s. net.

This edition has been prepared by a Committee of the Author's friends, consisting of: A. D. Waller, L.D. Wright, G.V. Anrep, J. Barcroft, F.F. Blackman, C. Lovatt Evans, W.O. Fenn, H.S. Gasser, J. Gray, D.T. Harris, H. Hartridge, Sir Edward Sharpey-Schafer, E.H. Starling. A photograph of the late Sir William Bayliss will be found in the volume.



"Bayliss's text-book is one of the select number of works which can be said to have exercised a direct influence upon the development of a science. Bayliss has been an irreparable loss to physiology, but his work, of which this book is the crowning achievement, will ensure that the record of his great teaching will remain."—BRITISH MEDICAL JOURNAL.

PHYSICAL CHEMISTRY FOR STUDENTS OF MEDICINE

By ALEXANDER FINDLAY, M.A., D.Sc., F.I.C., Professor of Chemistry, University of Aberdeen.
With 39 Figures. 8vo. 8s. 6d. net.

The great advances which have been made in recent years through the application of the principles of physical chemistry to the study of physiology, bacteriology, and other branches of biological science, underline the importance of medical practitioners having made it imperative for them to study it, or at least to acquire some knowledge of that branch of chemistry. In the present volume the aspects of physical chemistry which have found important applications in the medical sciences are discussed.

The Management of an Infant's Diet

The use of Mellin's Food in cases of Malnutrition, Marasmus or Atrophy

MELLIN'S FOOD 4 level tablespoonsful SKIMMED MILK 8 fluid ounces WATER 8 fluid ounces	*Analysis*	FAT	49
		PROTEIN	2 28
		CARBOHYDRATES	6 59
		SALTS	58
		WATER	90 06
			100 00

The principal carbohydrate in MELLIN'S FOOD is maltose, which it is admitted is particularly well adapted to the feeding of poorly nourished infants Marked benefit may be expected by beginning with the above formular and gradually increasing the MELLIN'S FOOD until a gain in weight is observed. Relatively large amounts of MELLIN'S FOOD may be given, as maltose is immediately available nutrition.

Mellin's Food

The limit of assimilation for maltose is much higher than for other sugars, and the reason for increasing this energy-giving carbohydrate is the minimum amount of fat in the diet made necessary from the well known inability of marasmic infants to digest enough fat to satisfy their nutritive needs

Samples, etc., free to Members of the Medical Profession from
MELLIN'S FOOD LIMITED, LONDON, S E 15

Combat Skin Diseases with Sphagnol

EPILEPSY AMBRIODIN

Doctors in Hospitals Infirmaries and other Institutions, and General Practitioners all over the country are prescribing

with excellent results in cases where other treatment has failed It quickly reduces the attacks without the undesirable effects which invariably accompany the administration of potassium bromide The patient's general health is not impaired but distinctly improved

A DOCTOR WRITES Patient was a man of 60 who for 40 years was subject to fits which years ad were of treatmei [illegible] the intervals between were prolonged till periods of three months intervened and then only assumed more of the *petit mal* form He was so convinced of their efficacy that he would not be without them (i e Ambriodin Tablets)

For recent Medical References see —*The Lancet* Sept 6th 1924 page 498 *The Prescriber* June 1924 *The Journal of Clinical Research* April 1924

Home Produced and New Zealand Dried Milks

The chief advantage claimed for the home produced dried milk over that imported from New Zealand is rapidity of transit between producer and consumer

In the winter this advantage cannot be claimed at this time of the year one of two things must happen Either the dried milk was prepared during the previous summer, and has been held in stock for sale during the winter, in which case the claim of rapid transit falls to the ground or the milk used in the winter is obtained from stall fed cows

VITAMIN CONTENT

Glaxo is prepared from the milk of cows which are out at grass all the year round in a country noted for its abundance of sunshine This is one of the reasons for the superiority of Glaxo A satisfactory dried milk cannot be made from the milk of stall fed cows numerous investigators having shown that the anti scorbutic, anti rachitic, and growth promoting properties of the milk are all markedly affected by diet and environment

CHEMICAL COMPOSITION

Home produced dried milks are not standardized chemically in Glaxo, which is standardized, the balance of fat, carbohydrate and protein is much nearer the ideal than in the home produced article

BACTERIAL PURITY

Whilst certain home produced dried milks are superior to others in this respect none of them can challenge the pre eminent position of Glaxo The average total bacterial count for a months samples of Glaxo has not exceeded 70 per c c for over a year for most months it has been much below this figure Glaxo is regularly tested by inoculation experiments for freedom from B Tuberculosis, and no positive result has ever been recorded.

GLAXO MEDICAL DEPARTMENT 56 OSNABURGH STREET LONDON N W 1

UNG. SEDRESOL (Ferris).

A Valuable Sedative Antiseptic and Healing Ointment.

UNG SEDRESOL is a combination of the tar products obtained by the destructive distillation of the wood and bark of the *Betula Alba* in combination with Oxide of Zinc and Antiseptics

It is specially indicated in Eczema, Psoriasis Erysipelas, Shingles, Erythema, Seborrhœa, Dermatitis, Pruritus Ani and Vulvæ, and in Inflammations and Eruptions of the Skin and in Burns and Scalds

UNG SEDRESOL is supplied to the Medical Profession at the following prices —

¼ lb Jars, **1/8** each ½ lb Jar, **3/-** each, 1 lb Jars, **5/9** each, 2 lb Jars, **11/-** each, 4-lb Jars, **21/-** each *(Empty Jars allowed for on return)*

Also issued in small Jars (without name) ready for dispensing or giving to patients —

No 1 size Jars (containing about 1 oz), **9/-** per dozen
No 2 size Jars (containing about 2 ozs) **12 6** per dozen
No 3 size Jars (containing about 5 ozs), **23/-** per dozen

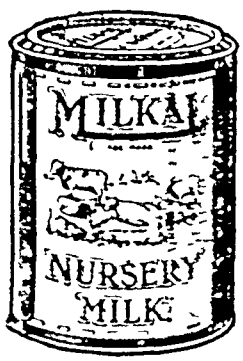
The Safe Analgesic

Clinical experience has demonstrated beyond doubt that Genasprin is a pure, safe brand of acetyl salicylic acid

Speedy in action, its work is accomplished without depressing the heart or upsetting the stomach

Guy's Hospital Gazette writes "Genasprin can stand upon its own merits, as its acknowledged purity is sure to make it widely appreciated"

St Bartholomew's Hospital Gazette writes "We have no hesitation in describing Genasprin as excellent Its purity is unquestioned . there is no doubt that many samples of aspirin on the market are far from being up to the B P standard Medical men prescribing Genasprin may rest assured that their patients are getting a particularly pure form of aspirin"



GENASPRIN

(The SAFE Brand of Aspirin)

A clinical sample of Genasprin will gladly be sent to any doctor upon application to

GENATOSAN, LTD., LOUGHBOROUGH, LEICESTERSHIRE.

As a Medical Man

Milkal is made in Devon at a Model Creamery under the constant supervision of Government Inspectors and Chemists

You will agree, we think, that it is more to your professional interest to know why—

MILKAL
THE CLEAN MILK

is so good a baby food than merely to **hear** that it is so

MILKAL is produced by a special process of drying rich cows milk by spraying it into a current of air heated to a certain temperature and by cleansing it of pathogenic organisms without making it sterile Complete sterilization as you know has effects upon milk which are more undesirable than the few harmless bacteria remaining in the finished product The ratio of the constituents of Milkal is that of the solids of rich cows milk

The chief advantages of Milkal are —

100% soluble in water

The fat in the milk thus obtained does not rise to the surface as in oily mass

Practically no coagulation of the Albumin

The Calcium Casein balance is undisturbed

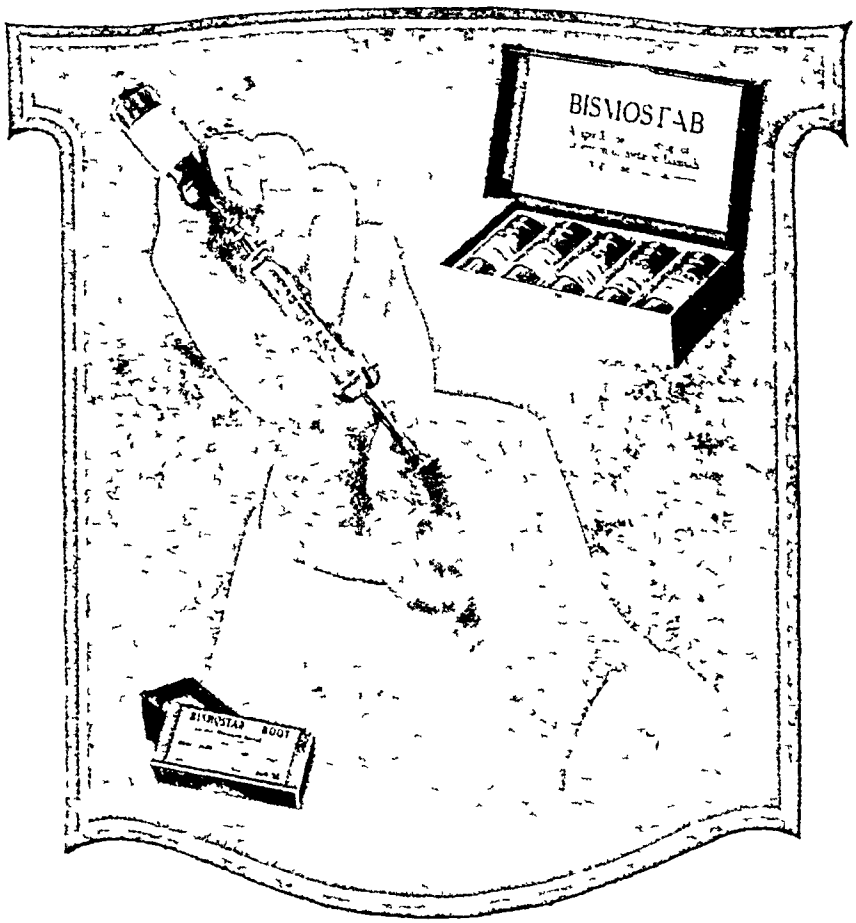
CRISTOLAX

PALLAS ATHENA

"Cristolax is a new, improved and entirely satisfactory method of administrating liquid paraffin, eliminating the disadvantages of the uncombined oil, and adding to the efficacy of the treatment It ensures natural and easy movement of the bowels and lubricates the whole digestive tract, enabling it to recover its normal tone and thus obviating the disturbing after effects which follow the use of ordinary aperients

Cristolax contains 50 per cent. liquid paraffin and 50 per cent. Wander Malt Extract and is presented in the form of granular crystals Extremely pleasant to taste it mixes freely with milk or water without separation of the oil The highly nutritive digestive and milk modifying properties of the Wander Malt Extract are retained unimpaired thus making the preparation a valuable addition to infant feeds



It mixes thoroughly with the intestinal content preventing formation of Scybala and does not cause over lubrication When added to cow's milk Cristolax prevents the formation of indigestible curds and supplies the deficiency of carbohydrate It can be administered to infants in the usual bottle feeds

"Cristolax is in daily use in many Infant Welfare Centres and Hospitals

A liberal supply for Clinical trial will be gladly sent on receipt of request

HEWLETT'S
ORIGINAL PREPARATIONS.

HORMONIGEN
(HEWLETT'S).

Hormonigen Tablets (Hewlett's) contain the hormones of the thyroid, pituitary, ovary, and testes.

Useful in Neurasthenia and all asthenic conditions, obesity, chronic cardiac cases, ephelis of the pluriglandular system and in anemia. In Amenorrhœa, Dysmenorrhœa, and at the Menopause Hormonigen is particularly effective, and even in chlorosis.

If there is high blood pressure, Hormonigen Sine Pituitary is indicated.

PRICE HORMONIGEN OR HORMONIGEN SINE PITUITARY,
3/3 PER 100, **30/-** PER 1,000

LIN. BETULÆ CO.
(HEWLETT'S).

Therapeutically equivalent to several times its weight of Sodium Salicylate without causing headache, tinnitus, &c. Has proved most useful in the external treatment of pure Rheumatism, Sciatica, Lumbago, &c. The external dose is about 1 drachm rubbed over the affected parts.

In 5, 10, 22, 40, and 90 oz. Bottles.
PRICE **10/6** PER LB.

IODERMIOL
(HEWLETT'S)

A bland emollient and non irritating preparation of Iodine, superior to the Tincture of Iodine in strength, yet causes no stain or inflammation of the skin after application.

It is easily absorbed under the influence of gentle friction. It does not harden the skin like the ordinary tincture, liniment and ointment, but leaves it soft and supple, and perfectly free from stain.

DIRECTIONS FOR USE.—Rub the affected part well with IODERMIOL until the Iodine is completely absorbed as indicated by the disappearance of the colour. The only residue left on the skin may be washed off if desired with soap and water.

PRICE **1/-** PER OZ. **14/-** PER LB.

VERONIGEN
Formerly known as MIST. VERONAL CO.
(HEWLETT'S).

A liquid Preparation of this prompt and reliable HYPNOTIC has long been desired, as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, and in ordinary cases of insomnia one fluid drachm of Mist. Veronal Co. (Hewlett's) is quite sufficient dose for an adult.

Dose for Adults.—One fluid drachm diluted about one hour before going to bed.

For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN, **10/6** PER LB.

MIST. PRUNI VIRG. CONC.
(HEWLETT'S)

A valuable stimulant and expectorant cough mixture, containing Carbonate of Ammonium, Ipecacuanha, Senega, Squill, and Syrup of Wild Cherry Bark. Quite free from Morphine, Opium, or poisons, so can be safely administered to children.

Dose 1 to 2 drachms diluted.
In 22, 40, and 90 oz. Bottles only.
PRICE **3/3** PER LB.

MIST. TUSSI RUB. CONC.
(HEWLETT'S)

A favourite and economical cough mixture, containing Hydrobromic Acid, Chlorodyne, Dilute Hydrocyanic Acid, &c. Most successful in allaying post influenzal coughs that are so persistent. One or two ounces added to water to make in 8 oz. mixture is one of the most effective and elegant mixtures that can be made, and the least expensive.

In 22 oz., 40 oz., and 8 lb. Bottles only.
PRICE **2/3** PER LB.

The Original & Standard Emulsion of Petroleum.

ANGIER'S EMULSION

PETROLEUM WITH HYPOPHOSPHITES

is made with petroleum specially purified for internal use It is the original petroleum emulsion—the result of many years of careful research and experiment

Influenza and Sequelæ

The unique soothing properties of Angier's Emulsion and its favourable influence upon assimilation and nutrition make it eminently useful both during and after Influenza. It has proved most efficacious in relieving the catarrhal symptoms, whether tonsillar, bronchial, or intestinal, also in combating the nervous depression and debility After the attack, or when the patient's nutrition and vitality are at the lowest ebb, try the continued use of Angier's Emulsion for convincing proof of its effects as a tonic and restorative

Bronchitis, Sub-Acute and Chronic

There is a vast amount of evidence of the most positive character proving the efficacy of Angier's Emulsion in sub-acute and chronic bronchitis It not only relieves the cough, facilitates expectoration, and allays inflammation but it likewise improves nutrition and effectually overcomes the constitutional debility so frequently associated with these cases. Bronchial patients are nearly always pleased with Angier's Emulsion, and often comment upon its soothing "comforting effects.

In Gastro-Intestinal Disorders

of a catarrhal, fermentative, ulcerative, or tubercular nature, Angier's Emulsion is particularly useful It exercises sedative, demulcent, lubricant effects throughout the entire intestinal canal, and it restores tone to all the digestive functions Moreover, it offers the very best vehicle for the administration of astringents and antiseptics (bismuth, salol, &c) The Emulsion may be administered undiluted or in any desired vehicle

on
SURGERY IN THE TREATMENT OF PULMONARY TUBERCULOSIS*

by
H MORRISTON DAVIES M D, M CHIR CANTAB,
F R C S ENG
MEDICAL SUPERINTENDENT VALE OF CLWYD ANATOMICAL CONSULTING SURGEON, UNIVERSITY COLLEGE HOSPITAL AND KING EDWARD VII WELSH NATIONAL MEMORIAL ASSOCIATION

SOME twelve to fifteen years ago and later remarks on this subject were almost completely confined to pneumothorax Even with this limitation the audience was apt to look askance at one, and a sound physician might show his soundness by asking "What is the pneumothorax treatment" or, "What are results" To have said at that time much about the further surgical possibilities when artificial pneumothorax failed was to run the risks of being thought so ultra-heterodox (some might say mentally aberrant) that one's influence in the technique of the simpler forms of treatment was likely to be seriously impaired Nowadays artificial pneumothorax is referred to familiarly as A P, in my place the slang term "gassing" is used Instead, moreover of having elaborately to expound the principles to general practitioners patients are sent to one definitely for this treatment

The other and, if I may use the expression more definitely surgical methods of treatment are not yet so widely recognized They are more serious they are associated with greater risks and they are still in this country far from being widely known or when known approved of In respect of these operations one is still looked upon with suspicion and even with disapproval, and the making of converts is a slow but very interesting process

Because of the general knowledge as regards artificial pneumothorax and the less general knowledge about the other surgical methods I propose to take up the subject at the point where pneumothorax fails to be complete, or fails altogether

The object of artificial pneumothorax is twofold (1) to rest the lung (2) to collapse the lung The relative importance of these two aims in different cases It the case is a fairly early one even if progressive rest is of more importance than collapse It is of course true that the more complete the collapse the more complete the rest but it does not follow that if collapse is partial only the rest obtained is of small value In some cases moderate partial collapse may be of the greatest value In the more advanced cases, on the other hand and particularly in chronic cases of long standing in which mechanical changes are well established and dilatation of the bronchi and cavities in the lung parenchyma are important and serious features the question of rest is of less importance than that of collapse The collapse, moreover, to be effectual must be fairly complete so far as the affected parts of the lung are concerned In haemorrhage moreover, if the bleeding is to be arrested by the pneumothorax the collapse must be such that it must involve *that part of the lung from which the blood is coming* In these cases, again, collapse is more important than rest

From the above it become clear that the presence of adhesions limiting collapse may not be of great seriousness in the treatment of those cases in which rest is the desideratum, but may completely ruin the value of the method in those in which collapse is essential even though the collapse may be equal to two thirds or the lung volume Statistics show, moreover, that the after results with complete collapse are most strikingly better than those where collapse is partial and is limited by bands and membranes and adherent patches

Apart from the consideration whether total collapse is necessary or not for the success in the treatment of any particular case, there are certain additional advantages gained by obtaining it The symptoms are more quickly got rid of, infection (in unilateral cases) ceases to be a constant danger bleeding is often more completely controlled, and the intervals between refill is *longer*

It becomes advisable, therefore in some cases, and necessary in others to divide when practicable those adhesions which are limiting collapse The adherence of the surface of the lung to the chest wall may be in the nature of a fusion of the two pleural membranes it may be by means of a broad membranous sheet allowing, but little separation, and often vascular *The adhesions may consist* of bands single or multiple varying in length and in size from the fine threads to cylindrical or flattened bands up to half an inch across The larger the adhesion the more likely is it to contain vessels of a size demanding respect in their treatment These band like adhesions may be attached to comparatively healthy lung or actually over a cavity They may have the appearance of starting direct from the surface of the partially flattened lung or the band may be part fibrous tissue part lung substance which has been drawn out into a cone In these cases it is often difficult to say by means of the x rays where lung ends and the adhesion begins though more possible by the aid of the thoracoscope Where fusion of the membranes has taken place division is not practicable in all other cases division may be possible but this cannot always be determined until the adhesion has been inspected

The diagnosis of adhesions between the visceral and the parietal costal pleural membranes is not in my opinion possible before a pneumothorax has been attempted unless it be by pneumograms as suggested by Deist Adhesions may be suspected as a result of the ordinary clinical and radiological examinations but that is all The adherence of the base of the lung to the diaphragm can, on the other hand be recognized when the dome of the muscle is distorted and flattened In such cases the dome will show an angle, or even be drawn into a point midway between the central tendon and the lateral costal attachments during inspiration some movement of the outer half of the dome will generally accentuate the angular deformity This type of distortion of the dome is not seen in cases of even extensive shrinkage of the lung if adhesions are absent It is naturally more frequently *observed on the right side*

The division of a single band like adhesion clearly defined by the x rays as a strand running across the pneumothorax from the partially collapsed lung to the chest wall is comparatively easy with a special long double-edged tenotome passed through an intercostal space the track having been previously anaesthetized with novocain This must be done in the x ray room the patient *being placed with the x ray* tube behind and the screen in front When the tenotome has been inserted the x rays are turned on the tenotome is directed so that the cutting edge of the blade rests on the adhesion which is then divided by slight sawing movements

When the adhesion is not so clearly defined or is large or is difficult of access and particularly when there are multiple bands or membranes *or the condition inside the* pleural cavity is somewhat obscure then the thoracoscope will give invaluable aid by enabling very precise knowledge of the state of affairs and relationship and character of the adhesions to be obtained With the vision obtained through the thoracoscope moreover, those bands or membranes which are found to be interfering with the collapse can be divided as and where required *by the galvano-cautery*

The technique is not particularly difficult, though practice is required in locating the adhesion in manipulating the thoracoscope with one hand and the cautery with the other and in deciding on the size of the band—the apparent size varies greatly with the distance from the lens Fortunately practice need not be at the expense of the patient as considerable skill can be *acquired by manipulating the instruments* inside a box across which pieces of string of various size and colour have been placed To those acquiring a thoracoscope and cautery I would make one suggestion it is as in mine the cautery is turned on and off by a sliding collar on the cautery handle have this fixed in the 'on' position and insert in the flexible wire a contact switch suitable for foot work

Details of the technique are as follows The table or bed on which the patient lies must be at a convenient height so

* Delivered before the Royal Institution of Great Britain [illegible]

that the surgeon can bend comfortably over the patient, to look down the thoracoscope when it is projecting two to three inches above the chest It is much easier to look down the thoracoscope when the light in the room is comparatively dim It is advisable to have a separate battery for both thoracoscope and cautery, it is also wise to have a resistance in each circuit

The thoracoscope is sterilized by standing it for some minutes in 1 in 20 carbolic acid, all other instruments are boiled All the instruments should be tested immediately before use The cautery when hot should give a red glow if too dark, the charred surface of the adhesion will stick to it, if too bright, bleeding from vessels will not be controlled

As a general rule it is simpler to insert the thoracoscope through the front of the chest In this position it is easy to look down it, and while the cautery is being introduced it can be left *in situ*, unattended if necessary, and will retain its position without falling over or dragging on the tissue The thoracoscope is inserted close to where the adhesion has been localized by the x rays, if there are multiple bands, some in the upper and some in the lower part of the thorax, it can be inserted between them The second or third intercostal space is the commonest site The cautery is best inserted in the axilla in the fourth or fifth intercostal space It is easier to work the two instruments if the cautery has to cross the thoracoscope to reach the adhesion

If the patient is nervous, a third of a grain of omnopon should be given beforehand The tissues of the chest wall through which the instruments must traverse are infiltrated with an analgesic I use 2 per cent novocain and adrenalin for this purpose I also make a puncture incision in the skin *to prevent the instruments dragging through it* Both thoracoscope and cautery are introduced through cannulas which are inserted through the chest wall by means of trocars

The thoracoscope is inserted first and a complete inspection of the interior of the pleural cavity is made Then, when the decision as to what adhesions shall be divided has been reached, the trocar and cannula for the cautery is inserted It is advisable to keep the patient at rest for at least sixty hours after the operation

When pneumothorax fails entirely or the amount of collapse obtained is insufficient to be effective, local or total collapse of the lung can still be obtained by other means

Collapse of the Base

Phrenicotomy and Evulsion of the Phrenic Nerve

If the complete nerve supply to one half of the diaphragm is divided, that dome will not only become paralysed and so be unable to influence expansion of the base of the lung, but it will in addition rise up into the thorax owing to the loss of all muscular tone The muscle is then influenced by the upward pressure of the abdominal contents and by the intrathoracic pull due to the natural retraction of the elastic tissue in the lung and the contraction of abnormal fibrous tissue This change of position will produce, or allow, a partial collapse of the lower lobe of the lung It has been found, moreover (Brunner), that during the ensuing months after the operation the dome of the diaphragm atrophies This allows of a still further rise, and also, therefore of a still further collapse According to Brunner and Felix, the rise of the right dome may be as much as 7 65 cm and that of the left dome 5 9 cm while the collapse of the lung may be equal to one sixth one-fourth, or even one-third of the volume of the lung It was to this end that the original operation of phrenicotomy was devised, the nerve being divided as it passed over the scalenus anticus muscle Results were often disappointing Sometimes a large phrenic nerve was found and then a fairly complete paralysis and a moderate rise of the dome into the thorax was obtained Frequently however the nerve bundle was small, and little or no change was noticed

The nerve supply to the diaphragm is mainly through the phrenic nerve which comes from the fourth cervical and occasionally obtains fibres also from the third and fifth cervical Motor fibres however run frequently in a bundle along with the nerve to the subclavius muscle W Felix has described a "doubling" of the phrenic nerve the second bundle of fibres may be 3 cm distant laterally from those which are taking the normal course This accessory phrenic he describes as taking the same course in the neck and in close association with the nerve to the subclavius It passes into the chest superficial to the subclavian vein, and then turns mesially to join the normal phrenic as it lies behind the innominate vein—the two nerves thus forming a loop round the subclavian vein This arrangement he describes as occurring in 20 to 25 per cent of cases The phrenic nerve is joined by fibres from the sympathetic in the lower part of the neck and also from the cochlear ganglion The twelfth intercostal nerve also supplies fibres direct to the diaphragm, but these are apparently of little consequence

Two operations have been devised to overcome the disappointments of simple division of the phrenic nerve

1 *Evulsion of the Phrenic*.—The nerve is exposed in the neck as it courses over the scalenus anticus muscle It is divided, and a secure hold is taken of the peripheral end An attempt is then made by steady traction to draw the whole nerve out from the thorax—that is to say, to pluck the nerve out from its insertion into the diaphragm When successfully accomplished the length of the nerve evulsed will be from 30 to 40 cm It will, moreover, have been torn away from connecting sympathetic fibres It will, in addition, bring with it the lower end of the accessory phrenic, when such exists Great care is required lest the loop formed by the phrenic and the accessory phrenic tear through the subclavian vein Other risks of the operation are haemorrhage, particularly from the pericardio phrenic artery and its two attendant veins which run through the thorax in contact with the phrenic In one case Sauerbruch had to remove two litres of blood from the thorax as a result of laceration of these vessels There is also the danger of tearing the lung and producing a pneumothorax or pyopneumothorax In cases where a pyopneumothorax already exists, there is the possibility that the pleura may get torn and the pus escape into the mediastinum Division of the vagus in mistake for the phrenic, death ensuing, has been described by Ziegler Failure to evulse the whole of the nerve is not unlikely when inflammatory processes and fibrous tissue formation have taken place at any point along the course of the nerve

As an alternative to this operation described by Felix, jun, and Lobsche there is—

2 *The Radical Phrenicotomy of Goetze*.—In this operation the phrenic nerve is divided low down in the neck the sympathetic fibres running to the inferior cervical ganglion are exposed by gentle traction on the phrenic, and are cut, as is the phrenic higher up again on the scalenus anticus, the nerve to the subclavius is also divided where it comes off the upper trunk at the upper and anterior border of the brachial plexus Both this and the preceding operation are done under local anæsthesia

The risks associated with the radical operation are theoretically slighter Actual experience shows, however, that the complications described is peculiar to the first operation occurs very infrequently

Goetze recommends his operation as a substitute for artificial pneumothorax when social reasons make refills impracticable Sauerbruch, Brunner, and others regard the paralysing of the diaphragm as the operation of choice in cases of tuberculosis of the lower lobe They advocate it in moderately severe or severe pyrexial cases when pneumothorax has failed, also in advanced but slowly progressive, slightly febrile cases, not entirely unilateral in which the question of thoracoplasty comes under consideration either because pneumothorax is from the first impracticable, or has been abandoned voluntarily and recurrence has taken place, or been abandoned involuntarily owing to progressive adherence of the pleural membranes Symptoms may be alleviated in advanced bilateral disease by unilateral paralysis on the more affected side Haemorrhage has been arrested by this operation Sauerbruch advises phrenicotomy should be done as a preliminary to thoracoplasty as a test of the capacity of the other lung to withstand the strain thrown on it by the major operation [illegible] this group of indications I would add intract[illegible] associated with cough in bilateral cases, or in b[illegible]

cases in which the left side is the more advanced One other condition is, I have long maintained, an indication for phrenicotomy I refer to cases of unresolved pneumonia which, unless some such prophylactic measure is taken, are likely sooner or later to lead to bronchiectasis

The results of phrenicotomy are, in general, considerable reduction of sputum and of cough and lowering of temperature Complete disappearance of symptoms must not be expected except in those cases where the disease is limited to the lower lobe Of 60 cases operated on by Sauerbruch 17 were improved none were healed Of 17 cases treated by Coetze, 7 were apparently healed, 9 were improved, and 1 was worse

COLLAPSE OF THE APEX

Apicolysis

This is the brief term which denotes artificial collapse of the upper part of the lung by mesial displacement of it together with the parietal pleura this layer of pleura having been stripped off the inner surface of the chest and the space thus formed being filled up by some foreign body, such as paraffin, fat, fibroids, muscle, etc

By this operation a fairly efficient collapse of the apex of the lung down to the third rib in the nipple line can be obtained The collapse, as in all operations other than pneumothorax, is permanent The objection to the operation is that it is necessary to introduce a foreign body into the extrapleural space formed by the separation of the lung and the parietal pleura from the deep surface of the ribs—otherwise the lung would at once re-expand There is possibly also slight risk in the operation of apicolysis that infected matter, squeezed out of the upper lobe may be inspired into the lower lobe An attempt to maintain this space by gas has been repeatedly made and found useless as the gas is too rapidly absorbed Paraffin is now used by Sauerbruch, Brunner, and others with varying degrees of success It has the advantage over living tissue that, when no complications occur, the volume of the paraffin remains unchanged and so also does the extent of the collapse On the other hand, complications are not infrequent The paraffin is an irritant and may give rise to an extrapleural effusion It is extremely difficult to prevent such an effusion from forcing its way to the surface through the wound and causing a fistula through which the liquid and the paraffin both escape and which sooner or later becomes infected Aspiration of the liquid before it has broken down the scar is difficult as the paraffin blocks the needle Once the fistula has formed it becomes necessary to remove the paraffin and to pack the wound with gauze to maintain the collapse of the lung Portions of two or more ribs may have to be removed later, to assist in maintaining the collapse and in the healing of the wound Another serious complication is the direct infection of the paraffin-containing cavity from the lung or the establishment of a communication between this extrapleural cavity and a cavity in the lung substance itself Baer does the operation through the front of the chest, while Sauerbruch and Brunner recommend the posterior route In neither case have the results been too encouraging

Many kinds of tissues have been utilized particularly by Tuffier, in place of paraffin—lipomata fibroids etc—and with a varying degree of success Living tissues transplanted into the extrapleural cavity diminish in volume during the first weeks or months There is a tendency therefore for the collapsed apex, together with any contained cavities partially to re-expand When fat is used, some of the fat may liquefy the liquid globules will work their way to the surface sometimes as long as two months after the operation causing a rise of temperature, pain, and a red swelling in the region of the wound If the skin is incised over this swelling the liquefied fat allowed to escape, and the wound kept aseptic it will heal there will, however, have been some loss of tissue and a corresponding re-expansion of lung I have recently tried to overcome this objection by the use of living pedicle grafts Briefly, the operation is as follows

An incision is made over the second costal cartilage and the adjacent part of the second rib These parts are exposed and excised The parietal pleura having been laid bare it is stripped off by the finger from the inner surface of the thorax, laterally, in front behind, and over the apex The lung gently pressed aside with the pleura collapses mesially and leaves an empty space which must be filled up by the graft In women the graft consists partly of fat from the front of the chest wall, but mainly when it is large enough, of the breast tissue on the same side The fat and breast tissue are tripped up in one long strip which is left hinged along the lower edge of the wound The lower end of the graft is then lifted up turned over, and tucked into the cavity, and the rest of the strip pushed in after it The divided edges of the pectoralis major are sewn over the attached end of the graft and the wound closed

In men there is usually insufficient fat and there is no breast tissue available I have, in one case, utilized the pectoral part of the pectoralis major muscle, detaching it from its connexions to the chest wall below the second rib and from its insertion into the humerus This part of the muscle has constituted the graft which has been tucked into the extrapleural cavity I have just recently seen this man six months after the operation, and have been very delighted with the efficiency of the collapse and the disappearance of symptoms There has been complete absence of any untoward result from transplantation of the muscle I feared lest contractions of the clavicular portions of the muscle should be accompanied by contractions of the graft, and that pain and discomfort would ensue There has been no discomfort whatever

The indication for apicolysis is that there is disease mainly localized to the upper lobe particularly that type of chronic tuberculosis which invades the whole upper lobe and shows little or no tendency to spread beyond and that type also in which there is cavity formation If the disease is clearly localized then I consider the operation to be preferable to attempting to collapse the whole lung by artificial pneumothorax on the ground that it is not a very serious operation, and when done there is no need for constantly recurring treatment, as with pneumothorax When however, the localization of the disease is less perfect and there is some invasion of the other lobe or lobes of that lung apicolysis is as indicated only when pneumothorax has been tried and failed and there are reasons against thoracoplasty Apicolysis is of value also in conjunction with pneumothorax when the upper part of the lung is adherent but the lower part is collapsed by gas

Results

The results of the seven cases on which I have done apicolysis have been as follows

1 Paraffin replacement for large apical cavity with retention of secretions Extrapleural effusion with escape of liquid and paraffin Permanent obliteration of intrapulmonary cavity but persistence of extrapleural empyema for which further treatment has been refused

2 Paraffin replacement Considerable improvement but the operation was not extensive enough

3 Fat replacement Liquefaction of some of the fat Incision aseptic healing of the wound and diminution of symptoms

4 Fat replacement No complications considerable improvement

5 Fat and breast tissue replacement Very great improvement

6 Fat and breast tissue replacement Two months later liquefaction of some of the fat Patient admitted to another hospital Abscess diagnosed and treated as such Readmitted under me Excision of part of two ribs Despite this there is considerable diminution of symptoms Under treatment

7 Muscle replacement Result most satisfactory

THORACOPLASTY

This is the biggest and the most serious of the operations for the treatment of pulmonary tuberculosis the results, however are so good that they fully justify the procedure It aims at producing almost complete and permanent collapse of the whole lung The collapse is not so complete as in a perfectly successful case of artificial pneumothorax, but it is superior to that in its influence on the disease because it is constant In pneumothorax the degree of collapse varies constantly, it may be complete immediately after a refill has been given but almost from that moment the lung begins again to expand and expansion continues until the lung is once more suddenly collapsed With thoracoplasty there is no variation Pneumothorax enables the lung to heal and when healed it may be allowed once more to function This is impossible with thoracoplasty, but the type of case selected for this operation has

usually reached that stage at which cavity formation or multiple dilatations of the bronchi make re-expansion, even after a considerable interval, undesirable

The operation is designed to collapse the whole of the chest wall together with the lung on the affected side The method of obtaining the result has changed since a decade and a half ago when the Wilms or Brauer-Friedrich operation was in vogue This change is mainly due to Sauerbruch, who recognized (and put in practice) the importance, above all else, of excision of the posterior parts of the ribs right up to the transverse processes of the vertebræ Variations of opinion exist as to the number of stages in which the operation should be done—as to the method of anæsthetization the amount of rib to be removed, and so on—but the essential principle stands

I cannot discuss the technique here I hope to publish that in full later Briefly, the operation entails the removal of portions of the posterior ends of the first ten or eleven ribs through a paravertebral incision A total of 110 to 140 cm of bone is removed The collapse of the chest wall is surprisingly immense, but the actual visible deformity of the patient when dressed and padded somewhat in the axilla is almost *nil* There is a considerable tendency to scoliosis, but this can be corrected by effort on the part of the patient

The results on the symptoms are often startling It is not uncommon to find immediate and complete cessation of all cough and expectoration One of my patients who had had incessant cough and sputum for two years despite continuous treatment, partly in a Swiss sanatorium and partly in this country, said that the complete disappearance of these symptoms from the time of the operation was alone worth the ordeal Another, who had his trachea drawn over to the affected side, complained that whenever he coughed his windpipe seemed to vibrate as a tense cord and that he had the sensation that sooner or later he would suffocate, this sensation disappeared directly after the operation, and this, combined with the cessation of cough and sputum, gave the greatest physical and mental relief

The operation, as is to be expected, is not always successful, it may be fatal It must be remembered, however, that most of the cases operated on would almost certainly get progressively worse until they succumbed, and that therefore every case improved or healed is a big gain to set off against those who die Considering the condition of those who undergo the operation, the mortality ratio is low

Sauerbruch has operated on 381 cases The mortality in the first week has been 14 per cent, while 35 per cent have been practically healed

Brunner, out of 117 cases, had an 11 per cent immediate mortality, 22 2 per cent were improved, and 41 9 per cent practically healed

Gravesen, out of 96 cases, had an 8 3 per cent mortality, while 21 9 per cent improved, and 14 8 per cent were much improved or practically healed

My own figures are much smaller Out of 25 thoracoplasties done for bronchiectasis and tuberculosis, 20 were for the latter condition Of these, 7 have become free from symptoms, 5 are considerably improved, while 4, still under treatment, bid fair to come under the "free from symptoms" group One case died of tuberculous enteritis eleven months after the operation One case only died immediately after the operation, and that case was complicated by a pyopneumothorax Previous to the operation on this patient about two pints of pus had to be aspirated every few days

If the above figures are combined, we have the observation that out of 514 patients who submitted to this operation, 237 derived very considerable benefit from it

Just as after pneumothorax treatment it is possible in many cases for the patient to return to work, so, too, is it possible for cases who have had thoracoplasty done But just as it is essential for patients with a pneumothorax to consider their health, be regular in their habits, and careful in their exercise and in the avoidance—if possible—of infections, so, too, is it the case with patients who have undergone the major operation

Cases suitable for this operation are selected from among those on whom pneumothorax has been tried and has failed *in toto*, or in whom the amount of collapse is inefficient and cannot be improved, also from those on whom a pneumothorax has been done and in whom the lung has re-expanded with return of symptoms and recrudescence of signs The greatest consideration must be given to the sound side In my opinion, any evidence of activity in this lung is a contra-indication to operation on the other This view is not held by all Continental surgeons Moreover, if, in the past, the less affected lung has been at all extensively implicated—that is, if there has been more than slight scarring or slight root involvement—there is too much danger from the strain that thoracoplasty will throw upon this lung Slight myocarditis is no bar to the operation, but the presence of additional disease, tuberculous or otherwise, elsewhere than in the larynx, is an absolute contra-indication I have already mentioned that Sauerbruch favours a preliminary phrenicotomy on the affected side as a means of obtaining information as to the ability of the sounder lung to withstand the strain of a complete thoracoplasty

PURULENT PNEUMOCOCCIC PERICARDITIS: PERICARDIOTOMY: RECOVERY.

BY

ARTHUR J HALL, M D, F R C P,

PROFESSOR OF MEDICINE, UNIVERSITY OF SHEFFIELD,

AND

VINCENT TOWNROW, F R C S,

ASSISTANT SURGEON, SHEFFIELD ROYAL HOSPITAL

THE number of cases in which a purulent pericarditis of pneumococcal origin has been successfully opened and drained is not large This is not to be wondered at, seeing that the condition is only one item in a serious general infection, and its very presence points to an extension beyond what occurs in most cases Apart, however, from its interest in this respect, this case is exceptional in the time at which the pericardial infection began

On September 23rd, 1923, a youth, aged 17, whilst walking in the country was suddenly seized with dizziness and acute pain over the left front of the chest He had difficulty in getting home As the pain became more severe he was admitted to hospital on September 25th the third day of disease He was then in great distress and there were signs of pericardial effusion It was impossible to examine the back of the chest as the slightest attempt at movement caused extreme embarrassment to the breathing, and much distress He vomited at frequent intervals He was collapsed and grey with a moist skin The tongue was furred There was herpes on the lower lip His temperature was 102 8°, pulse 140, and respirations 40

On September 26th he was no better in spite of treatment, and paracentesis was decided upon The area of cardiac dullness was much increased to both sides The heart beat could be felt indistinctly, well within the left edge of the dullness, and for a short period a pleuro-pericardial friction sound was heard at the upper part of the left border When examined again a few hours later it had disappeared

Paracentesis pericardii was performed (V T) The needle was introduced in the fifth space 1½ inches from the sternum, passing backwards, slightly upwards and inwards, and 300 c cm of sero-fibrinous straw coloured fluid were drawn off This gave immediate relief After its removal pericardial friction sounds were heard over the upper part of the dullness The fluid contained many polymorphonuclear leucocytes with Gram positive diplococci, pneumococci were obtained culturally

During the next three or four days the temperature fell gradually to normal He slept well, the breathing, though still frequent, was not distressing There was no cough or sputum The herpes became more marked Occasional pleuro pericardial friction was heard just inside the left nipple line, also bronchial breathing in the left upper chest in front, and pleural friction in the left axilla There was also some dullness with diminished breath sounds at the left base behind

On October 1st the ninth day of disease he was listless and apathetic He was a bad colour and the pulse remained frequent in spite of the fall of temperature The liver edge could be felt 1 to 1½ inches below the costal margin and there was epigastric tenderness The pericardium was therefore again aspirated and 200 c cm of thin purulent fluid removed This was again followed by dennite pericardial friction sounds Later in the same day it was decided to drain the pericardium This was again followed under local anaesthesia (alypin) and one inch of the fifth left costal cartilage excised The internal mammary vessels were retracted inwards and the pericardium was opened (V T) A considerable quantity of thin purulent fluid escaped A drainage tube was inserted passing behind the heart After this he improved in his general condition The pulse came down considerably He began to eat his food The wound discharged freely the pus becoming much thicker He also developed a cough which caused some pain In spite of this however the temperature which had been subnormal at the time of the operation continued the rise which had begun two days after this

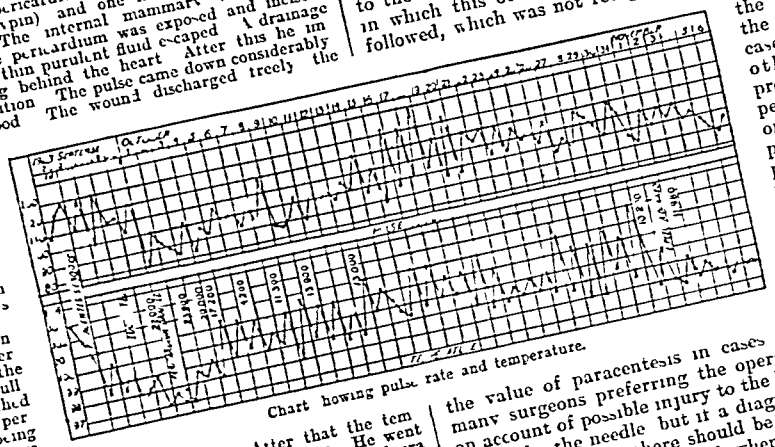

Chart howing pulse rate and temperature.

As the pleura continued it was determined to explore the left base where dullness and diminished breath sounds persisted and pus being found the left pleura was opened and drained on October 31st The empyema was a very small one After that the temperature fell to normal and he made a steady recovery He went out on December 11th apparently in excellent health The pleura had healed up some time before the pericardium ceased discharging At the present time nearly a year after his attack he is in robust health He is able to carry on his work just as before He plays football without any discomfort whatever The apex beat is slightly outside the nipple line The scar which is about an inch to the right of this is slightly retracted with each systole but there is no retraction at the apex There is no murmur

As a rule pneumococcal pericarditis is diagnosed, or overlooked, as the case may be, at some time after pulmonary symptoms have established themselves in characteristic fashion In this case it was fully developed and causing mechanical distress by the third day Whether there was also an initial infection of the lungs or not must remain uncertain, but if so it could hardly have preceded the pericardial infection Neither the temperature nor the general appearance of the patient suggested a pneumococcal infection, although the presence of herpes and the pulse-respiration ratio corresponded to what is seen in a pulmonary infection There was a striking absence of cough during the first week, and indeed a pneumococcal infection was not suspected until the bacteriological report on the fluid was received

In a very incomplete reference to the literature no definite case of a primary pneumococcal pericarditis of this severity has been found, or one in which surgical measures have been necessary on the fourth day of infection Attention has of recent years been called to the possible danger of injury to the left pleura at operation and Connor[1] reports a case in which this occurred, with the result that an empyema followed, which was not recognized during life, and proved fatal This may be the explanation of the empyema in our case, but on the other hand the presence of pleuropericardial friction on the left side prior to the first paracentesis shows that this pleura had not altogether escaped early infection

There is a tendency in the literature to depreciate the value of paracentesis in cases of pericardial effusion many surgeons preferring the operation of pericardiotomy on account of possible injury to the heart or coronary vessels caused by the needle but if a diagnosis of pericarditis with effusion is correct there should be little risk Paracentesis is easy and quick and relief, when the fluid has been drawn off, is immediate the operation of draining the pericardium can then be carried out in more favourable circumstances This was the procedure adopted in our case The oblique sinus was not drained, as recommended by Ballance and yet there was a complete recovery Possibly there is less necessity for drainage of this space in cases met with in civilian practice than in those occurring as a result of war wounds In support of this view one may instance the comparative success of arthrotomy for septic infections in civil practice, when compared with the unfavourable result of this operation in joint infections met with in war wounds

EARLY PREGNANCY AND EPITHELIOMATA

BY

C W A EMERY, M B, B CH, B A O,

WEST CLIFF-ON-SEA

Do the conditions prevailing in the first three months of pregnancy assist in a study of the etiology and treatment of epithelomata? It is in the hope of eliciting an answer to this question or at any rate of inducing others to consider the suggestion contained therein that I have written the following notes

It has always seemed to me that a clue to the cause and treatment of epithelomata through the conditions to be found in early pregnancy has never been given the care and thought to which it is entitled There is no other normal condition in which one tissue if it does not definitely attack at least invades another so that unless every possible clue fails we ought not easily to be turned aside and pronounce it a blind

The fundamental point to be kept in view in a study of any disease is that the normal human body is fully equipped to withstand disease and it should be our duty to find out in the first instance why its resistance fails—not the nature of the attacking force Remember that the tissues are fully equipped at the start therefore the weakness is on their side Working from this standpoint we would have to allow that the body tissues are prepared to, and normally can, resist the growth of tissues are prepared against this particular growth that will resist any invading growth whether malignant or no This leads me to suggest that as a result of this preparedness the body will resist the normal invasion of the chorionic epithelium The chorionic villi are able to invade the uterine wall and so in some way this resistance has been overcome—but how? That the body shows signs of a reaction taking place is evidenced by the general malaise nutritional disturbances and sickness of pregnancy We also know that lutein cells have appeared in the ovary after the ovum left it and these cells seem to grow in proportion to the rate of growth of the placenta and that when the placenta ceases to grow, at the third month these lutein cells also cease to grow That there is some connexion between these two points is admitted It is also generally admitted to-day that the function of the corpus luteum is that of an internal secreting gland When Frankel found that destruction of the corpus luteum in pregnant rabbits resulted in abortion, he concluded that it produced a secretion which maintained the implantation and growth of the ovum *in utero* I suggest that this might be modified by saving that the secretion produces a body reaction, the result of which is to provide an antibody to the normal body resistance to any invasion," and so the chorionic epithelium is able to maintain its hold, and that Fränkel's experiment allowed the normal body resistance full play, that the chorionic epithelium was repelled

Pregnancy sickness is evidence of this auto-inoculation and also explains the abnormal lutein activity found in

chorionic epithelioma. Overproduction of secretion results in completely antidoting resistance, and so invasion continues wildly. Underaction or inaction is a cause of sterility. Further, the action of lutein secretion in lowering or countering body resistance explains the preponderance in women of cancer cases under the age of 40, as compared with men under that age. The body must be primarily regarded as fully equipped, yet there is a weakness here and a clue to general resistance may follow deduction. The epithelioid character of the lutein cells and the fact that they contain a lipoid substance is important when we remember that the body is prepared to resist an attack by epithelial cells. My meaning, however, will be clearer if I diverge for a moment.

It seems a very important point to me that in the body generally we do not find an epithelioma growing where there is an unadulterated layer of fat below epithelium. I use the word "unadulterated" advisedly. The commonest sites for epithelioma are to be found where the epithelium comes into direct contact with mixed muscular or fibro-muscular tissue—for example, in lip, tongue, cervix uteri, and following dissolution of continuity of a fatty layer by wounds, ulcers, burns, etc. A case of cancer of the abdominal wall would be rare in this country, and yet among the women in India who carry burning incense next their abdominal skin, and so get large sores with a breaking down of the fat layer, it is common. It must be noted, too, that the only area which the body normally prepares for the reception of invading cells (chorionic epithelium) does not possess a fat layer. Fat, therefore, is protective. Muscular tissue, especially mixed muscular and fibrous tissue, has some property which makes it a very receptive medium for proliferating epithelium.

That epithelial and lipoid substances come so much into evidence in early pregnancy and produce some form of reaction on the part of the body, and that the fat of the body ordinarily exercises a protective action, are very important points. When I refer to "unadulterated" fat I mean fat which is not interlaced with elements such as I have said form suitable receptive media—for example, in the breasts. The action of fat may be purely mechanical: it may act as a protective blanket—we have evidence of germs taking advantage of this in the fatty envelope of the tubercle bacillus, and, to digress again, a method of attack on this envelope, preparatory to antituberculous treatment, is here indicated—but the close relationship of fat and epithelium in the body generally and the epithelial and lipoid nature of the lutein cells suggests that either fat alone, or some interaction between the two, provides the blood with its resisting powers, or, again, that the fat in itself provides both mechanical protection and the resisting powers to the blood normally, and that, in a finer and more intimate form, in the lutein cell epithelial and lipoid substances evolve an antidote to that resistance.

I do not think that impregnation of the ovum by the spermatozoon and subsequent events are in any way analogous to a proliferating epithelial cell, as I have seen suggested. An analogy would require the production of innumerable ova, *not* the much more highly specialized and complex result we get. The "microbe" is the epithelial cell itself, and its proliferation is the result of one of known methods. If, while proliferating, this cell is in contact with mixed muscular tissue, it is in contact with a new food, and sometimes intensive cultivation results. The epithelial cell, like any other living entity, will go in search of nourishing food, and, finding it, will greedily absorb it. This food being a vital constituent of muscle food, starvation and exhaustion result, with subsequent death.

The preventive treatment of cancer is of extreme importance, and is along the lines of greater internal and external body hygiene. An impaired drainage system must result in a lessened vitality of the body cells, and consequently impaired functional and resisting activity. Further treatment would follow a closer study of the exact uses of fat and isolation of the agent capable of producing increased body resistance, in conjunction with early diagnosis and its use after operation.

In conclusion, then, my answer to the question at the beginning of this paper would be in the affirmative.

British Medical Association.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

T. GRAINGER STEWART, M.D., F.R.C.P., President.

DISCUSSION ON THE DIAGNOSIS AND TREATMENT OF COMPRESSION PARAPLEGIA.

OPENING PAPER

BY

ANTHONY FEILING, M.D., F.R.C.P.,

Assistant Physician to St. George's Hospital, Physician to the Hospital for Epilepsy and Paralysis, Maida Vale, and to the Royal National Orthopaedic Hospital.

THE subject for our discussion to-day, the diagnosis and treatment of compression paraplegia, is one which must appeal to the general practitioner as well as to the neurologist and the surgeon. Any form of paraplegia which is amenable to surgical intervention demands careful attention, and an early and accurate diagnosis is an essential preliminary to successful treatment.

We must first define what we mean by the term "compression paraplegia." For the purpose of this discussion I will define it as follows: "A pathological condition where a localized lesion causes pressure either on the whole contents of the spinal theca or on the spinal cord alone, with or without involvement of the nerve roots, in such a way that the functions of the spinal cord become progressively damaged."

In order to keep this subject within reasonable limits I am deliberately excluding from consideration cases of sudden or acute lesions of the spinal cord, caused by trauma or acute myelitis of any kind.

It is not of academic interest only to pause for a moment and inquire exactly how the functions of the spinal cord suffer—that is, how the symptoms are produced. For symptoms will often, indeed generally, arise some time before the cord is actually mechanically compressed or squeezed. The conditions are very different from those obtaining in, say, cases of gunshot wounds of the cord, with suddenly produced lesions which may entirely destroy the cord over one limited area. Here the interruption of function is complete physiologically and often anatomically as well. Ascending and descending degeneration of nerve tracts follow, and subsequent recovery depends primarily on the extent to which such secondary degenerations have occurred. But the morbid anatomy, as well as the conditions found at operations during life, show very conclusively that no such complete anatomical lesions exist in the majority of cases of compression paraplegia. Witness also the recovery, often complete recovery, which may take place after a successful intervention.

Microscopic examinations again demonstrate the exceedingly small amount of secondary degeneration which may be found even in cases which have shown a complete paralysis during life. Obviously, therefore, some factor must be at work other than the mere mechanical destruction of nervous tissues. This factor is almost certainly interference with the circulation in the cord. Probably the veins suffer first in most cases, with the production of a state of venous congestion. Later the arteries suffer, and an ischaemia or anaemia of the cord occurs, which, though insufficient to cause permanent degenerative changes, is yet enough to produce very considerable, even complete, temporary loss of function.

There is yet another factor to be considered, and one which is sometimes of great importance. This is the fluid

pressure exerted by a collection of cerebro-spinal fluid, encysted or at any rate dammed up by chronic adhesive meningitis, or sometimes caused by blocking of the circulation of the fluid in the subarachnoid space by a tumour within the dural envelope

Now what are the possible causes of compression paraplegia, using that term in the sense which I have defined already? We may attempt a classification as follows

Extrathecal Lesions

A Diseases of the bones
- 1 Pott's disease
- 2 Caries sicca
- 3 Tumours—(*a*) primary (*b*) secondary
- 4 Spondylitis deformans
- 5 Osteitis deformans

B Extrathecal lesions other than diseases of the bone
- 1 Aneurysms of the aorta
- 2 Parasitic cysts
- 3 Tumours arising in the perithecal tissues—for example sarcomata

Intrathecal Lesions

1 Tumours—
- (*a*) Extramedullary Fibromata sarcomata endotheliomata psammoma myxoma or haemangioma
- (*b*) Intramedullary tumours

2 Chronic meningitis
- (*a*) Pachymeningitis
- (*b*) Meningitis sero-circumcincta

The general signs and symptoms are best considered under two heads first those due to the direct effect of the lesion on the spinal cord and nerve roots at some particular level and secondly those due to interruption of the functions of the long ascending and descending tracts in the cord We may use the terms "local" and "remote" to designate the two groups of symptoms

The local symptoms are due to involvement of the nerve roots and some particular segment or segments of the cord Of these local symptoms those due to affections of the nerve roots, both posterior and anterior, are often the more important as they may constitute the earliest symptoms, and of these the symptoms referred to the posterior roots are the more constant Pains localized to the area of supply of the roots involved are a very common and characteristic feature, and may precede for some time any signs of pressure on the cord itself Usually more or less constant, these pains are subject to paroxysmal attacks of increased violence often induced by movements or by such a common and simple act as coughing or sneezing If the dorsal roots are involved on both sides a well marked girdle sensation may be present Associated with the pains sometimes is hyperaesthesia or hyperalgesia (better perhaps termed over-reaction) in the same area, and this condition may be followed later by a loss of sensation even when the pains persist—an example of the so-called anaesthesia dolorosa The existence of these root pains has a great practical importance, for it is not very uncommon to see a patient in whom useless operations have been performed for the relief of supposed renal calculi or appendicitis when a careful examination of the nervous system might have avoided this calamity

It is less common on the whole to find symptoms specifically referred to the anterior roots When present these consist in localized muscular atrophies or paresis with loss of the corresponding reflexes Occasionally involuntary muscular spasms may precede such wasting or weakness of muscles Such signs are generally best seen in cases of disease of the cervical region of the cord, for the changes are then easily studied in the musculature of the hands and arms The local symptoms referable to the spinal cord may be as follows (1) On the motor side, localized muscular atrophies and paresis with loss of tendon reflexes and sometimes vasomotor and trophic changes (2) Sensory symptoms, these may consist in a loss or diminution in sensibility confined to the particular distribution of the affected segment or segments, this sensory change may be of the so-called dissociated type, so typically observed in syringomyelia When a loss of sensation is present below the level of the lesion it may be difficult to separate the exact limits of the two areas of sensory impairment

Of greater interest is the occasional presence of pains *referred to parts below* the apparent site of the lesion—for example, pains in the legs in the case of a compression of the dorsal region of the cord This condition has been the subject of a good deal of comment recently, being entitled 'pains of central origin' but its occurrence was clearly pointed out by Horsley as long ago as 1911

The remote symptoms—that is, those due to interference with the conduction of the nervous impulses in the long tracts of the cord—may be considered under three heads (1) *motor*, (2) *sensory*, and (3) *autonomic*

The motor symptoms consist, first in a loss of voluntary power This may vary from a slight weakness to a complete loss of all power It is usually first apparent in the more distal parts of the limbs and affects the flexor muscles more than the extensors, a loss of power of dorsiflexion of the feet being one of the earliest signs Severe ataxia or inco-ordination is not as a rule found when enough voluntary power is present to test the movements The loss of power is generally gradual and progressive but occasionally a very rapid paraplegia sets in, notably in certain cases of Pott's disease where a complete paraplegia may sometimes be attained in as short a time as twenty-four hours Under a discussion of the motor symptoms must be included the state of tone of the muscles of the limbs—a point of great interest and importance

The commonest picture is what is known as a spastic paraplegia in extension The legs gradually become stiff, this stiffness spasticity or increase in tone affecting the extensor muscles of the lower limbs more than the flexors, hence the legs will be rigidly extended at the hip- and knee-joints with plantar flexion of the feet it being remembered that the calf muscles are physiologically to be regarded as extensors This increase in tone of the extensors may be so extreme as to render even forcible flexion of the limbs a matter of some effort As compression increases and the functions of the cord become progressively impaired this spastic paraplegia in extension may be seen to pass gradually into a spastic paraplegia in flexion with the limbs flexed at all joints

An earlier stage of this condition is the occurrence of *those painful flexor and adductor spasms which may constitute* an annoying and even distressing symptom The gradual passage therefore, of a case from one of spastic paraplegia in extension to one in flexion must be held to be a sign of ill omen

A flaccid paraplegia in cases of compression of the cord is far less often seen It may *however, occur as one of two* varieties (1) as the final stage of a complete compression where all physiological continuity in the cord is broken, and (2) exceptionally as an initial and sometimes temporary state In this second form it may herald the appearance of a rapidly fatal compression or it may be followed by improvement with the change to a spastic state With this early flaccidity an acute or rapidly produced lesion is present

Alterations in the reflexes are the next item for consideration under the head of motor symptoms These alterations may be rapidly summed up as follows Exaggeration of the tendon reflexes often with clonus a loss of the normal superficial reflexes, and the appearance of certain new forms of reflex activity Thus the knee-jerks and the ankle-jerks will be exaggerated, often with patellar or ankle clonus the abdominal and cremasteric reflexes will be lost if the lesion lies above the level of their reflex arc in the cord The normal plantar flexor response is replaced by the so-called extensor response or sign of Babinski Associated with this (Babinski's sign) is the "*flexion reflex*," which consists in a movement of flexion of the whole limb This may be seen to occur in a rudimentary form in the shape of the contraction of the flexors of the thigh even when this contraction is insufficient to move the knee joint appreciably This reflex flexion movement is best elicited by some slightly noxious stimulus, such as dragging a pin along the outer part of the sole of the foot Indeed, Babinski's sign is only part of the general flexion movement As compression increases the reflex excitability of the lower limbs becomes increased and the threshold of stimulation necessary to produce this flexion reflex is lowered, as the

same time the field from which it is possible to excite the reflexes enlarged Hence the frequent and irritating flexor movements or flexor spasms to which attention has already been directed, and which in severe cases may be produced by almost any handling of the lower limbs

In those more rare cases where the paraplegia has finally become flaccid, or where it has been flaccid from the first from the initial spinal shock, all reflex activity below the lesion is entirely abolished A useful generalization, however, emerges from what has been said on this question of the changes in tone and in the reflexes It is this A change from a spastic paraplegia in extension with exaggeration of the tendon reflexes to a state of flaccidity with great diminution or a loss in the tendon reflexes is a sign of grave import, indicating a progressive loss in the functions of the cord, whereas a change from an initial flaccidity to one of spasticity in extension with exaggeration of the reflexes is, on the other hand, a favourable sign

We must now consider the remote sensory symptoms It is a general rule that loss of sensation appears later than loss of motor power At first the feet and legs are affected most and the loss becomes less marked and less absolute higher up, thus in a lesion at the mid-dorsal level, for example, the sensibility above the thighs may be practically unimpaired Complete loss of all forms of sensation is relatively less common, except in the later stages of the disease A distinct dissociation of sensation may be found in some cases Generally the senses of position and passive movement and the vibration sense are affected before pain and temperature, and sensibility of light touch is usually the last to go Occasionally there is a relative preservation of sensation in the lower sacral segments when the loss is complete in all higher segments Unless a complete loss be present, a distinct variability both in the exact level and in the degrees of the loss is not uncommonly found, especially if the lesion causing the compression is diffuse and extends widely in a longitudinal direction

This general sketch of the symptoms applies to cases where the compression has been exercised on the whole cord more or less evenly Obviously there are many cases, and especially cases of intradural tumour, where the pressure is exerted at first on one side of the cord only, with the production of either unilateral symptoms or a more or less characteristic Brown-Séquard syndrome

The last division of the remote symptoms which remains to be considered is the affection of the autonomic system especially in relation to bladder and rectum, of the practical importance of which I need hardly remind you If the damage to the cord occurs above the lumbar and sacral regions and the roots of the cauda equina are not affected, the earliest bladder symptoms to occur are a difficulty in beginning the act of micturition, in most cases this soon gives way to retention of urine, which, indeed, not infrequently occurs quite suddenly If such retention be not relieved by the passage of a catheter or by suprapubic drainage overdistension of the bladder takes place, the sphincter relaxes from time to time, and dribbling of urine occurs If, however, overdistension be prevented, a certain amount of automatic action of the bladder may be expected to develop This will as a rule only occur in cases where the compression has been of gradual onset and where the functions of the cord have not been unfavourably influenced by the presence of urinary infection or bedsores Such automatic action may result in the involuntary discharge of urine at varying intervals Should the lesion be low down in the spinal canal and affect either the sacral segments of the cord or the roots of the cauda equina, the parasympathetic supply of the bladder will be interfered with, and, as a rule, instead of retention with possible later automatic action the sphincter of the bladder becomes paralysed and persistent dribbling of urine results In some instances even here a periodic reflex micturition is developed

The functions of the sphincter of the rectum are generally affected at the same time as the bladder Obstinate and increasing constipation is the rule, and when this is relieved by aperients or enemata control over the subsequent evacuation is lost Should the lesion involve the origin of the sympathetic nerve supply of the small intestine or the parasympathetic outflow for the innervation of the lower bowel, a paralytic distension of the abdomen may result—a condition which may be aggravated by the weakness or absolute paralysis of the muscles of the abdominal wall In severe lesions affecting the sacral segments the sphincter of the rectum may be completely paralysed

Other groups of symptoms coming under the head of the autonomic system are (*a*) vasomotor changes, (*b*) abnormalities of sweat secretion, (*c*) trophic lesions, and (*d*) finally, alterations in the functions of the pilomotor centres Time will only allow me to refer very briefly to this interesting series of changes

Abnormal vaso-constriction may be evident in an unusual pallor and coldness of the paralysed limbs, vaso-dilatation by some swelling or blushing of the skin, which is generally seen in the more acute cases The anomalies of sweat secretion usually consist in a tendency to hypersecretion in the paralysed parts, the level of the lesion in the cord has in some instances been demonstrated by the injection of pilocarpine Head and Riddoch have further demonstrated an excessive sweating as occurring as part of the fully developed flexion reflex or mass reflex in cases of severe injury to the cord, where the lower part of the cord below the lesion has taken on an increased reflex excitability Trophic lesions in the shape of bedsores are, unfortunately, only too familiar a symptom, which needs no description As a rule the more severe the compression the greater the liability to bedsores, and often one of the earliest results of a successful intervention is the healing of a sore

With the foregoing sketch of the general features of compression paraplegia in our minds it will be convenient now to describe briefly the peculiarities of some of the more important forms of the disease—and Pott's disease of the spine, or spinal caries, claims first attention, as being the commonest form of compression paraplegia About 5 per cent of all cases show spinal cord symptoms, which may occur at any age, and it is important to note that nervous symptoms may appear before any disease of the vertebral column has been suspected The cord may be injured in one of several ways—by pressure from an abscess, by the growth of tuberculous granulation tissue interfering with the circulation in the cord, by the formation of a dense chronic pachymeningitis, and finally, though very rarely, by the direct pressure of a displaced fragment of bone

With regard to these different forms of lesions in Pott's disease, Sorrel and Sorrel-Dejerine have lately pointed out that the form of paraplegia due to the pressure of an abscess tends to appear earlier, becomes more rapidly complete, and is attended with a better prognosis, while that due to a pachymeningitis appears more slowly, is progressive, and is ultimately the more incurable lesion In the majority of cases the onset is gradual and the compression progressive up to a certain point, but occasionally, and especially in elderly people, a complete paraplegia may set in quite suddenly In the slighter cases nothing may be noted beyond a slight weakness of the legs with perhaps some spasticity, increased tendon reflexes, and extensor plantar responses In more severe cases a typical paraplegia in extension will be found Root pains are not as a rule present, the loss of sensation is generally not extreme is often variable in degree, while its upper limit is characteristically fugitive and difficult to estimate accurately Exceptionally the paraplegia is flaccid from the beginning, in these cases the paralysis is usually of rapid onset and the prognosis grave

The next form of compression paraplegia to which I would make especial reference is that produced by spinal tumours Setting aside secondary tumours of the vertebral column, the commonest form of tumour is the intrathecal and extramedullary tumour, which arises inside the dural envelope, often in connexion with a nerve root, and exercises pressure on the cord over a particular segment or segments This is a lesion which is essentially amenable to cure by surgery, provided the diagnosis has been made sufficiently early Experience has taught me that the incidence of such tumours is much underestimated by the profession at large Many cases are allowed to drift into incurable and hopeless paraplegia for lack of an early diagnosis The only reason for this condition appears to be

a lack of appreciation of the possible existence of such a lesion

The clinical picture of these extramedullary tumours is that of a "slowly progressive spastic paraplegia, with early defined sensory loss often preceded or accompanied by well marked root symptoms and not infrequently with a tendency to the development of the Brown Sequard syndrome" (Lorin) In its most typical form the history of these cases is divided into three chapters First, a period characterized by root pains, often severe and paroxysmal, it is at this stage that the disease is most likely to be confused with quite different conditions, such as angina pectoris or renal calculus and various futile operations performed Secondly, a period where weakness of one or of both lower limbs appears accompanied by disturbances of sensation or the Brown Sequard syndrome Thirdly, a complete spastic paraplegia

I have already alluded to the character of these root pains, and will say no more about them now except to emphasize the importance of keeping in mind the possibility of the existence of a spinal tumour when pains of this kind are complained of The exact distribution of these pains is of course, often of great value in the topographical diagnosis of the lesion The symptoms produced by pressure of the tumour on the cord will follow more or less closely the description already given of compression in general But the frequency of a predominantly unilateral motor weakness with objective sensory loss mainly on the opposite side of the body (the Brown Sequard syndrome) is sometimes a characteristic feature In the earlier stages the objective loss of sensibility is apt to be more of the dissociated type where the sensations of pain and temperature are affected more than the sensation of light touch With the advance of the compression a typical spastic paraplegia in extension becomes evident, generally with great exaggeration of the tendon reflexes and a well marked flexion reflex as already described

In cases of long standing there are certain features in the disturbances of sensation which are worth remarking Besides the root symptoms the objective loss of sensation is generally very definite and extends to a perfectly well defined level At the upper border of this level of altered sensation there may often be found a zone of hyperaesthesia or a band where all forms of sensation are completely lost Even in severe cases it is to be noted that the sensibility in the sacral segments of the cord tends to be relatively less affected In these cases of extramedullary tumours a steady progress in the symptoms is the rule though signs of complete compression may be delayed for many months even years The actual nature of the tumour does not influence the variety or the course of the symptoms as much as its position—whether anterior or posterior to the cord or on its lateral aspect—except in so far as a rapidly growing tumour will obviously produce symptoms more rapidly

Much of my time has necessarily been occupied by a consideration of the signs and symptoms to be found in any case of compression paraplegia I have also discussed quite briefly the typical features of two special forms of this disease—spinal caries and extramedullary tumours I hope therefore that it is not necessary to enter deeply into the question as to whether in any given case a compression lesion is present or not There are, however, certain diseases which may simulate a compression paraplegia very closely These are spinal syphilis, disseminated sclerosis and syringomyelia A chronic syphilitic meningomyelitis may give very much the same clinical picture as we have described indeed there may actually be a certain amount of compression present from meningeal thickening Examination of the blood and of the cerebral spinal fluid may be needed to settle this point But it may be mentioned that a positive Wassermann reaction in the blood does not negative the existence of a spinal tumour, and a positive reaction in the spinal fluid has also been found in some cases of spinal tumour

There are, however other changes in the spinal fluid which are very typical of spinal compression of which an account will shortly follow Clinically, signs elsewhere in the nervous system, and especially changes in the pupils or cranial nerves, would naturally speak for syphilis and against tumour It is however, in certain cases of disseminated sclerosis that the greatest difficulty may arise Examples of the so-called spinal type of disseminated sclerosis with a spastic paraplegia and perhaps a little loss of sensation confined to the periphery of the legs do certainly exist, but it is wise not to be content too easily with this diagnosis In coming to a conclusion due weight must be given to the history, to the presence or absence of remissions or relapses, and to any affection of the cranial nerves, and especially of the eyes, and nystagmus alone cannot be accepted as conclusive evidence of disseminated sclerosis, for it has been found in lesions of the cervical part of the cord of many different kinds On the other hand root pains with a steady progress in the symptoms unrelieved by any remissions speak more strongly for a compression

Syringomyelia, though it may simulate a compression lesion in the cervical region, may generally be distinguished by the marked and persistent dissociation of sensation of its extreme chronicity, and by the late affection of the sphincters It is with greater difficulty separated from an intramedullary tumour, with which indeed, it is often practically identical in its nature and effects The final diagnostic test is afforded by lumbar puncture and examination of the cerebro-spinal fluid This is so important an aid that its use should on no account be omitted in any case where the slightest doubt exists

If we have excluded any general disease of the nervous system and have arrived at a definite diagnosis of a local lesion, two important questions then remain to be answered—the nature and the site of the lesion In considering the nature of the lesion our first step is to discover whether it is a disease of the bones of the vertebral column or not whether it is within or without the thecal sac Due regard must be paid to the history of the illness as well as to the results of the clinical examination This last must be very complete, and besides the ordinary neurological examination must include a careful examination of the spine, an examination of all the bodily system not forgetting the possible presence of some such lesion as an aneurysm of the aorta, and especially the possibility of a vertebral lesion being due to a secondary deposit of malignant disease, a careful search for the presence of a primary growth must therefore often be made X-ray examination of the spinal column is imperative, and may be combined, as will be described later, with the method of injection of lipiodol into the theca

The very important point of lumbar puncture and examination of the cerebro-spinal fluid must now be considered The changes occurring in the fluid in compression of the cord are often highly characteristic and may afford conclusive evidence of a block in the free circulation of the fluid in the spinal subarachnoid space Since Froin described a condition where the cerebro-spinal fluid was coloured yellow and clotted spontaneously on standing much has been written on this subject I can here only summarize the conclusions which we can draw from recent work One of two characteristic changes or series of changes is to be found in the fluid as withdrawn from the subarachnoid space below the site of the compression First the fluid may be, as normally, colourless, but contain a great excess of protein without any excess of cells—a condition to which the French have given the name of dissociation albuminocytologique" And secondly, and more rarely, the syndrome proper of Froin may be present where a yellow or golden brown colour of the fluid may be noted (xanthochromia), with a tendency to spontaneous and massive coagulation of the fluid, this coagulation taking place very rapidly after withdrawal The first of these changes the increased protein content, is certainly an earlier occurrence than the latter, which is not always found even in cases of severe or complete compression Indeed the estimation of the protein content of the fluid may be said to give a good index of the severity of the compression Bearing in mind the normal figures of the albumin content—namely, from 0 025 to 0 04 per cent—we can attach importance to figures of over 0 1 per cent which are by no means uncommon, indeed, figures of 1 per

cent have been recorded These changes are only found in the fluid below the compression, a fact which has led to the discovery of the value of a double puncture in some cases—one in the lumbar sac at the usual site, and the other above the supposed site of the lesion, usually in the cisterna magna through the occipito-atlantal ligament, after the method introduced by Axel An interesting comparison can then be made between the two fluids and definite confirmatory evidence of compression obtained

Recently Sicard has introduced a new method of radiological diagnosis which is useful in determining the presence or not of a block in the subarachnoid space, and secondly, its exact situation and magnitude This consists in the injection into the cisterna magna of a substance called lipiodol, a vegetable oil containing 40 per cent of iodine, which is very opaque to the x rays The lipiodol is very heavy and in a normal subject sinks rapidly to the bottom of the theca, where it is clearly demonstrated by x-ray examination If a block be present the lipiodol will be arrested for a varying time at the level of the block, hence the upper limit of the block may thus be clearly defined By injecting the lipiodol into the lumbar sac and inverting the patient the lower limit of the block may be similarly shown I will leave it to other speakers to discuss the exact details of this procedure and will only emphasize the value of this method, especially in cases where the topographical diagnosis of the lesion is not definite by neurological tests alone It is well to add a word of warning that cisterna punctures should not be undertaken without preliminary practice on the cadaver In the majority of cases a careful neurological examination is sufficient to establish an accurate diagnosis of the level of the lesion, in arriving at which the following considerations may be borne in mind

Localized root symptoms have a decided value, whether they consist of pains, of anæsthesia, or of localized muscular atrophies But in the majority of cases the topographical diagnosis rests in the main on the exact distribution of the sensory loss The value of this depends very much on whether a clear and definite upper level of altered sensation can be elicited If this is present a good localization can be established If, however, the upper level of the sensory loss gradually shades off into an area where sensation is only partially lost—a hypæsthesia—an exact diagnosis becomes more difficult In such cases the border between the absolute loss and the partial loss is usually taken as the level of the lesion Some observers place greater reliance on the level of the loss of temperature sense Occasionally it is possible to distinguish a zone of hyperæsthesia abutting on the upper level of the sensory loss If so, this has a localizing value

It is less common for a topographical diagnosis to be possible from the motor symptoms In lesions of the cervical part of the cord, however, muscular atrophies in the hands or arms or in the muscles of the shoulder girdle may afford exact information, as may also the results of electrical examination of the muscles A careful examination of the tendon reflexes in the arms particularly is often of great value, for these will be normal above the lesion, abolished at the level of the lesion, and exaggerated below the lesion A knowledge, therefore, of the segmental representation of the reflex in the cord is essential, though this can always be verified by reference to a textbook In lesions in the dorsal regions differences in the upper and lower abdominal reflexes and between the power in the upper and lower segments of the recti muscles have an obvious localizing value

There are many points of detail in the diagnosis of the nature, the extent, and the site of the lesion which could be elaborated in far greater detail than I have attempted I hope that other speakers will complete these gaps in my remarks and will deal more specifically with treatment, which is essentially a surgical problem

May I, finally, be allowed to repeat my conviction that many cases of chronic compression of the spinal cord go unrecognized until it is perhaps too late to achieve a cure or even much improvement? For this reason alone our subject demands close and careful investigation

GENERAL DISCUSSION

Dr HILDRED CARLILL (London) supplemented Dr Feiling's paper with some remarks based upon his own experience The special interest of compression paraplegia at the moment was due to the recent introduction of methods which facilitated the determination of the upper and lower levels of the compressing agent, and in some cases its nature A fracture of the spine, notably in the cervical and lumbar region, might occur without causing cord compression Fracture-dislocation might be present without impairing the palpable outline of the spinal column In many cases of traumatic cord compression there were obvious reasons by which the level of the cord injury might be diagnosed A photograph of a case was shown illustrating the attitude characteristic of a lesion directly below the sixth cervical segment In addition to the segmental distribution of sensory loss, the pectorals, triceps, forearm and hand muscles, abdominal muscles, and lower limbs were paralysed On the other hand, certain muscles of the upper limbs, notably the biceps, supinators, and deltoids, were not only not paralysed but were in a state of contraction from irritation of the fifth and sixth cervical spinal roots directly above the lesion In the photograph, the upper limbs were seen abducted and flexed at the elbows, the intercostals were paralysed, respiration depending on the diaphragm alone A colleague had found a fracture-dislocation between the seventh cervical and first dorsal vertebræ

Sometimes in affections of the upper two dorsal segments, and indeed throughout the cervical cord, they might find ocular evidence of sympathetic palsy Similarly in the dorsal cord, the lumbar enlargement, the sacral region, and in the conus and cauda equina, a compressing lesion usually gave specific evidence of its regional distribution Vasomotor disturbance was common in lesions of the dorsal cord Priapism was often quoted as a feature of cervical cord lesions, but it occurred frequently with lesions of the dorsal cord, and was ascribed by Kocher to vasomotor disturbance Of four cases of stricture involving the dorsal cord under Dr Carlill's own care there was priapism in two, and in one of these it persisted throughout the illness—six months, the intensity of the lesion was at the fifth dorsal segment In a case of fracture of the twelfth dorsal vertebra priapism occurred rapidly and was relieved by laminectomy A feature of some cases of cord injury was excessive sweating from an area of skin which varied with the level of the lesion If the injury was above the second dorsal segment the whole body might sweat, but the sweating area was mostly on the head, neck, arms, and upper part of the trunk With a lesion about the fourth dorsal segment the head and neck might be dry but the rest of the body wet A lesion at the level of the ninth dorsal segment might cause hyperidrosis over an area which corresponded roughly with that of the sensory impairment, and with lesions below this level the sweating area was apt to be less than that of the anæsthesia

Dr Carlill next showed two photographs (1) A case of compression paraplegia from stricture which affected chiefly the fifth dorsal segment The lower limbs were flexed at the hips and knees, and this attitude persisted after death It would be recalled that paraplegia in flexion occurred with lesions which affected not only the pyramidal tracts but the extra-pyramidal tracts as well The effect on the latter tracts was to abolish the reflex tonus of the palsied extensor muscles without interfering with the reflex activity of the paralysed flexor groups (2) A case showing that even a huge bedsore could recover if the cause of the palsy was effectively tackled The man had syphilitic meningomyelitis with sudden onset of paraplegia The disease, the palsy, and the sores were all cured permanently The local treatment of the sore was by sunshine

A man of 43 was at present under Dr Carlill's care whose lower limbs had been affected since he had cerebro-spinal fever in 1917, the disability had become progressively worse during the last two years The clinical diagnosis was compression paraplegia from a lesion at the sixth dorsal segment, a meningitis serosa circumscripta originating from the cerebro-spinal fever The lumbar puncture needle

filled with cerebro spinal fluid but no fluid could be persuaded to flow The fluid from a low dorsal puncture contained 0 02 per cent total protein and 17 lymphocytes per cubic millimetre Lipiodol was injected through a high dorsal puncture, and the radiogram showed the lipiodol held up at a point opposite the body of the seventh dorsal vertebra At the operation there was found a considerable fluid swelling covered by thickened arachnoid when this was removed a quantity of cerebro spinal fluid gushed out and the compressed spinal cord with its vessels came into view A bougie was then passed upwards and the subarachnoid channel found to be free The passage downwards was obstructed by another cystic swelling which was also removed The man had made definite but slow progress The cord had been compressed for a long time below the site of compression it had suffered probably more from obstruction to its blood supply than from deprivation of its cerebro- spinal fluid It would be recalled that the anterior spinal artery and the two posterior spinal vessels are in the central portion of the vertebral If the cerebro spinal fluid was not a nutrient of the cord a feeble circulation of it as regards both rate of flow and quantity was without significance The diagnosis in this case was made on the history and clinical evidence and was supported by the failure to obtain cerebro spinal fluid by lumbar puncture It was confirmed by the lipiodol injection and the x rays and proved by operation *Although the ultimate freedom* of the subarachnoid channel had been proved by the passage of the bougie it was still impossible to collect cerebro-spinal fluid by lumbar puncture two months after the operation The cerebro spinal fluid from a low dorsal puncture on June 26th 1924 contained 12 lymphocytes per cubic millimetre globulin in definite excess and 0 14 per cent total protein

For a few years physicians had been in the habit of comparing the chemical composition and the cellular content of samples of cerebro-spinal fluid taken from below and above the site of a suspected block in the subarachnoid space This differential examination from the point of view of the fact of compression of the cord rather than from that of the nature of the compressing force had lost some of its value now that they had lipiodol but as cerebro-spinal fluid was necessarily withdrawn from whatever site the lipiodol was injected it was convenient to examine it Even if lipiodol were not used to demonstrate the lower level of the compression, he had always withdrawn when possible some cerebro-spinal fluid in the preliminary survey of the case Authors were accustomed to recommend that lipiodol should be injected into the cisternal space to demonstrate the upper level of an obstruction Cistern puncture was an occipito atlantal puncture the thickness of tissue traversed in the adult was about 5 cm and the space between the dura mater and the medulla, when the needle was inserted at the correct angle, was nearly 3 cm The chief uses of cistern puncture were three (1) for the collection of cerebro-spinal fluid from above a block in the subarachnoid space (2) combined with lumbar puncture, for the irrigation of the subarachnoid space, (3) for therapeutic injections or the injection of lipiodol *In health the* cerebro-spinal fluid from the cistern and lumbar regions was identical The pressure was the same and the subarachnoid space could be proved to be a free channel The lumbar cerebro-spinal fluid was *sometimes normal below the* site of proved compression In cases of subarachnoid block the lumbar cerebro-spinal fluid might differ from that from the cistern The pressure relations also varied, this variation had proved to be of greater importance than the variation in chemical composition, etc., because changes of the latter type might be caused below the site of degenerative changes in the cord and apart from compression Lipiodol had rather usurped the place of the former contrasting of specimens of cerebro-spinal fluid For the purpose of demonstrating the upper level of a block with lipiodol it was necessary only that the injection should be made above the block It did not matter how high it was made As a rule they were able from clinical evidence to determine the segmental level of the upper part of the lesion, it was less easy with the lower Lipiodol not only gave the relation of the lesion to the bones, but it indicated whether obstruction was complete or partial As with everything else, cistern puncture was easy enough for those who knew how to do it and who had had opportunities of practice But there were and there would continue to be, physicians who had neither the knowledge nor the experience Moreover, some patients had necks which it was inadvisable to puncture by reason of acne, carbuncles or other sepsis In these, lipiodol might be injected by cervical or dorsal puncture It should be remembered that lipiodol once injected took a long time to disappear from the subarachnoid space, and this fact militated against its further use after, for instance, an operation had been performed for the purpose of removing a block He had seen one case of septic meningitis subsequent to lumbar puncture

On three occasions Dr Carlill had failed to withdraw cerebro-spinal fluid by lumbar puncture One was the case of circumscribed serous meningitis previously described Another was somewhat similar, in which a lesion of the cauda equina supervened on an attack of tetanus Both these cases had received the appropriate intrathecal treatment, but it was unlikely that treatment caused the condition which were found In the tetanus case it was only in the lumbar region that failure to withdraw cerebro-spinal fluid occurred, and this in spite of the fact that a general anæsthetic was employed The fluid higher up was *healthy The third case* was that of a boy with a pineal cyst It should be remembered that failure to withdraw cerebro-spinal fluid or to assess correctly its pressure might be due to obstruction anywhere between the cerebral ventricles and the point of exit of the needle

Dr Carlill doubted the accuracy of Dr Fearnley's statement that apart from syphilis a true positive Wassermann reaction in the cerebro-spinal fluid was found in some cases of spinal tumour In cases of meningitis due to causes other than syphilis the Wassermann reaction in the fluid was often positive provided that the serum reaction was positive His cases had been chiefly sarcoma fractures with dislocation syphilitic meningitis and tuberculous caries It was noteworthy that at operation and also at autopsy the cord in some cases had appeared to be intact *and untouched by the compressing agent although signs of* paraplegia had been obvious In a case in which sarcoma involved the lumbar and also the cervico-dorsal spine there was general weakness and a bedsore but no reflex, sensory or sphincter abnormality In none of four cases of sarcoma was there any cells in the cerebro-spinal fluid, but each fluid contained excess of globulin Of two cases of tuberculous lumbar caries, the fluid of one was healthy in the other there was excess of globulin but no cells It was useful to carry a bottle of saturated solution of ammonium sulphate to test for excess of globulin A rough determination that there was an excess might be made by noting the amount of froth on shaking the tube

He had had but one case of true xanthochromia with massive coagulation The lesion was syphilitic meningitis affecting chiefly the lumbo-sacral region When faecal incontinence and retention of urine were added to painful weakness of a lower limb, the former diagnosis of sciatica was doubted The cerebro-spinal fluid contained 364 polymorphs and 116 lymphocytes per cubic millimetre The fluid in these cases of massive coagulation contained not only an increase of albumin, but also a type of albumin usually absent—namely fibrinogen Xanthochromia needed to be distinguished from the yellow colour of former haemorrhage In a case of carcinoma affecting the cauda equina, secondary to disease of the breast, the first few drops of cerebro-spinal fluid were yellow After a small movement of the needle the subsequent fluid was perfectly colourless It contained 11 lymphocytes per cubic millimetre, excess of globulin, and 1 05 per cent albumin Incision of the distended dura mater relieved the pain Two or more tubes should always be ready A valuable and ready method of counting cells with the ordinary haemocytometer was described by Baker in a report on cases of syphilis of the nervous system by Hildred Carlill Fildes, and Baker in the *Journal of the Royal Naval Medical Service* October 1917 From the standard of the amount of information to be gained by the procedure at the time and in the laboratory be regarded

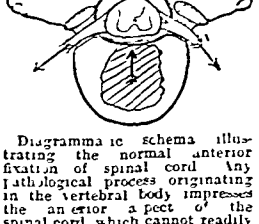
diagnostic thecal puncture is the most important operation in medicine From the patient's point of view, freedom from pain and after effects was urgently necessary From the physician's standpoint they were equally necessary, especially in view of the probable necessity to repeat the operation not once but many times The pathologist wished for a fluid without a single red cell produced by operative trauma These various considerations—pressure, quality, colour, "dry tap," etc—made it clear that the operation should be performed only by the expert or under his supervision If the patient did not see the needle and did not hear it spoken of he should be unaware that one had been used

In conclusion Dr Cahill wished to suggest that greater care should be taken of terminology in describing physical signs "Babinski normal" had no meaning presumably what was meant was "Plantar response flexor" "Plantars in excess" conveyed nothing to the mind "Knee jerks brisk (or absent), no ankle clonus," likewise conveyed very little, for it did not tell us whether the ankle-jerks were present or abolished, if they were absent, of course, there could be no clonus Lastly, a too ready use of five diagnoses should at all times be avoided—they were neuritis, lumbago, rheumatism, sciatica, myalgia

Dr J W Burrow (Leeds) emphasized the occurrence of vertebral rigidity in cases of spinal cord tumour, and showed a case of extramedullary spinal tumour, successfully operated upon by Mr Daw of Leeds, as an illustration in the discussion He considered small qualitative and quantitative changes in sensation of the utmost importance in diagnosis, and advocated the use of Head's algesiometer for the purpose of sensory examination Agreement was expressed with the opener of the discussion in his statement that paraplegia due to tumour pressure often went undiagnosed He also mentioned cases of paraplegia following slowly upon a slight trauma, knowledge of them pathology was sought The fact that a positive Wassermann reaction was occasionally obtained with highly albuminous cerebro-spinal fluids—almost certainly non-syphilitic—was commented upon Dr Burrow expressed some dissatisfaction with lipiodol as an aid in diagnosis He had seen retention of urine follow its use, and would only employ it in a few very difficult cases

Mr Geoffrey Jefferson (Manchester) said that as regards the cerebro-spinal fluid in paraplegia, in general, any pathological process which compressed the cord interfered with the ready passage of cerebro-spinal fluid alongside it Whether the compressing agent was outside the theca or within it, stasis in the distal or caudal portion would equally occur, and evidence of this stasis would be discoverable in the chemistry of the fluid These changes in the cerebro-spinal fluid might be summarized as falling under the following headings (1) changes in colour, (2) changes in chemical composition, (3) changes in pressure With regard to the first point, he was interested to hear that a true Froin's syndrome, a xanthochromatosis with rapid massive coagulation, had been so rarely met with He had seen it so far in its most characteristic form once only—a case in which a vertebral growth had invaded the canal equally with complete cerebro-spinal block Changes in the constitution of the fluid occurred with stasis, but they were apt to be more profound with intradural tumours than with extradural For when the blocking agent, usually a tumour, lay within the theca the albuminous and salt exudates from that tumour passed directly into the cerebro-spinal fluid These exudations were presumably given off from all surfaces of the tumour, from the upper no less than the lower, and hence xanthochromia or albuminosis might be present in the fluid above as well as below For this reason changes in chemistry and colour did not necessarily mean that the fluid tested had been withdrawn from below the growth But since in the fluid below the tumour stasis was added, the cerebro-spinal fluid changes would be more profound If the fluid, then, was very definitely abnormal, there was strong presumptive laboratory evidence (ignoring for the moment the clinical signs) that the tumour was above the point of puncture It went without saying that this would generally be the case, since the ordinary lumbar puncture was made between the fourth and fifth lumbar vertebrae, and the whole of the cord lay above The point was worthy of consideration, however, for they did not yet know to what extent the cerebro-spinal fluid was altered by stasis alone and to what extent it was changed by exudations from tumours or exudations within it The hard fibroma or endothelioma, for instance, could hardly influence the composition of the fluid profoundly by "weeping" into it

With regard to spinal fluid pressure a simple test could be employed Normally, any rise in cerebral venous pressure showed itself readily and rapidly in an accompanying rise in cerebro-spinal fluid tension Thus, a cough, or a straining with the mouth closed, caused a rise in cerebro-spinal fluid tension The same effect could be produced in a more controllable manner by compression of the jugular veins in the neck (Queckenstedt's manœuvre) In the presence of a complete spinal block the rise in cerebro spinal fluid tension would not be transmitted to the distal portion If the block were only partial the rise would be delayed This test, like any other single test, was corroborative only, but it was of considerable physiological interest It was very little extra trouble to attach a manometer to the lumbar puncture needle before collecting fluid, and to try the effect on cerebro spinal fluid pressure of congestion in the head It was not generally necessary to compare this with the fluid pressure obtained by high spinal or cistern puncture, although the comparison of the two made the picture complete Ordinarily one could obtain sufficient information from noting the latest period before any rise occurred, and the extent of that rise when it took place (see Ayer, *Arch Neurol and Psych*, January, 1922)



In connexion with lipiodol there was already a considerable and a growing literature So far no serious ill results following on its proper use had been described, and for that reason the cases mentioned by Dr Burrow were of considerable interest Much had still to be done in the precise observation and recording of its effects One of Mr Jefferson's patients had a temperature of 104° F the evening of the injection, but no further reaction occurred There was no block present in this case, and the cause of the pyrexia was obscure Lipiodol was always described as being very considerably heavier than the cerebro-spinal fluid, but Sicard had evidently realized himself that it was not so heavy that it would fall like mercury In his last paper he advocated waiting an hour before the x-ray photograph was taken in order to admit of better gravitation, for it was certain that droplets were held up by the slightest obstruction This delay was wise, and seemed to be a strong argument in favour of high injection as against low injection and inversion of the patient Lipiodol was a valuable adjuvant, a help in diagnosis, but no more Whether they were using it a trifle too enthusiastically they should learn from their collective experiences

With regard to paraplegia in spinal tuberculosis, one could not think of spinal tuberculosis without associating with it the name of its original observer, the terms in which he announced his discovery were of peculiar interest to a neurological section Pott, in his original paper ("Remarks on that kind of palsy of the lower limbs which is frequently found to accompany a curvature of the spine," etc), gave a good account of slowly developing spastic paraplegia He made particular note of adductor spasm, and even described involuntary movements Pott taught the profession to treat this condition, and though his methods might seem to us to have been brutal in the extreme (rest is not mentioned in his papers) he began to obtain cures, and took an optimistic view of the prognosis of this form of paraplegia This attitude had been fully justified by the subsequent history of this complaint, for to-day it showed a higher percentage of recoveries than any other form of paraplegia The actual incidence of palsy in vertebral tuberculosis was probably somewhere about 5 per cent Taylor and Lovett give it as 13 per cent (*Med Record*, 1886), but Charlton Wallace, in a recent and valuable statistical summary, found 79 paraplegics in 1,649 cases of spinal caries treated at the New York Hospital for the Ruptured and Crippled—that is, 4·7 per cent (*Journ Bone and Joint Surgery*, 6, 1924) Paralysis was certainly on the decline owing to the more efficient treatment of spinal tuberculosis to-day Thus it rarely developed in

children undergoing treatment though it might occasionally appear even then. Paraplegia in adult Pott's disease was a much more serious affection no doubt because it signified extensive bone involvement. Further, a correct diagnosis was often delayed, for spinal deformity might be absent. Most surgeons had seen cases of Pott's disease in adults where treatment had been carried out for a year or more on a diagnosis of rheumatism, fibrositis, or osteo-arthritis—diagnoses that had been corrected only by the appearance of a lumbar or psoas abscess.

Since the rational treatment of this form of paraplegia could only properly be appreciated by a knowledge of how the paralysis was brought about some discussion of this point was inevitable. Pott himself insisted that it was not the deformity itself which caused the spinal compression, and that it was not due to bone pressure. Charcot (*Leçons de Mardi*, 1888-89) held that it was due to pachymeningitis, "pachymeningite externe tuberculeuse" whilst recently Sorrel and Sorrel Dejerine (*Rev. Neurol.* 1924), as Dr. Feiling had said, discriminated between the modes of onset of the paralysis when the cause was abscess and when the cause was pachymeningitis—rapid in the former and slow in the latter. These authors also printed an excellent photograph of a case of cord compression by bone in an old Pott's disease, lest we were tempted to forget that such a thing was possible.

The problem of laminectomy in Pott's disease was an ancient one, and, whereas at one time surgeons were enthusiastic in its favour, the bad results which had followed ill-conceived operations had chilled enthusiasm. To-day they would generalize by saying that laminectomy was not indicated in carious paraplegia, but he thought all would make reservations. The chief argument against it was that 80 per cent. of cases recovered the use of their limbs with conservative treatment alone (Wallace). What of the remaining 20 per cent.? Where the paralysis remained stationary, or even increased after strict immobilization had been instituted, laminectomy would have to be considered. Certainly this might offer the only hope if serious sensory loss was developing. But these cases were fortunately uncommon. As a rule improvement followed very rapidly on immobilization of the spine with hyperextension and sometimes cure of the paralysis, but not of the disease, was effected within three months. Operation was most likely to do good when abscesses were present in the vertebral canal less likely to be of value when the cause of the palsy was a pachymeningitis.

Diagrammatic schema illustrating the normal anterior fixation of spinal cord. Any pathological process originating in the vertebral body impresses the anterior aspect of the spinal cord which cannot readily move backwards.

Mr. Jefferson's views on the place of laminectomy in Pott's disease were based on the surgical anatomy and means of fixation of the cord. Normally, fixation was effected by means of the issuing nerve roots passing on and into the intervertebral foramina. These roots ran in a definitely forward direction (see figure) and laced the cord on to the vertebral column much as encircling branches fixed ivy to the trunk of a tree. This anterior fixation was assisted by the close connexion between the anterior surface of the dura and the posterior common vertebral ligament. Further, when the body was flexed and especially if a localized kyphosis existed, the cord was brought into still more intimate contact with the bodies of the vertebrae. Behind, the cord was relatively free and the dura had no connexion with the ligamenta subflava or laminae, from which it was separated by a pad of cellular and adipose tissue. The cord was, therefore, particularly vulnerable on its anterior surface from any injury or disease of the bodies of the vertebrae, for it could not readily move away from them. A collection of fluid or caseous material or of granulation tissue on the backs of the vertebral bodies would impinge very readily on the cord itself. Whether this was the cause of motor paralysis being an earlier manifestation than the sensory changes he could not say. It had always seemed to him to be a question of functional physiology rather than a point in vascular supply. Possibly its pathology was a mixed one. It seemed very probable, however, that the most benign cases of paraplegia—those in which an improvement in the condition of the limbs followed in a few days of extension and fixation—there had not been even an external pachymeningitis. In these cases a collection beneath or involving the posterior common ligament projected backwards against the cord, forming an elevation, which would be mechanically enhanced by the collapse of the anterior parts of the vertebral bodies at that point. This explained why many laminectomy operations had been futile. The pressure was not exerted by the laminae themselves, but by a pathological process compressing the front of the fixed cord. Many excellent drawings illustrating these points were to be found in Alquier's valuable paper (*Nouv. Iconog. de la Salpetriere*, 19, 1906). The operation of laminectomy was to be undertaken with a clear conception of the objects aimed at. Removal of the laminae alone was useless. The most successful cases would be those in which an abscess was found in the vertebral canal, cases where there were masses of granulation tissue would be less favourable, and some attempt should be made to curette this tissue from the backs of the vertebrae. This required the greatest gentleness and no little experience of cord surgery. No attempt should be made to treat radically the bone condition, the object of the operation was the relief of cord compression and not the cure of the vertebral disease. The operation itself was to be carried out with the most complete haemostasis and the utmost gentleness which the surgeon could command. Care must be taken not to carry the bone removal so far laterally as to interfere with the zygapophyses else the stability of the back might be so far jeopardized as to lead to disaster.

In conclusion, Mr. Jefferson endorsed Dr. Feiling's remarks on the lamentable manner in which many cases of advancing spinal paralysis were allowed to progress to a hopeless condition. Spinal tumours and brain tumours were much commoner than was generally believed and they should all be on guard lest they escaped notice.

The President (Dr. GRAINGER STEWART) dealt with some of the surgical aspects of compression paraplegia. Chronic leptomeningitis did not improve permanently with operation. The compression of the spinal cord was probably due to a fluid pressure rather than to the meningitis. Once encystation was temporarily restored within twelve hours of operation.

In cases of intrathecal tumour the most frequent position for the tumour was between the anterior and posterior roots and attached to one or the other. The onset of the symptoms in such cases was very typical, and was due to purely mechanical causes. No compression would result until the tumour reached a sufficient size. It was not important to recognize these tumours as they were easily removed and the results of operation were excellent. As the tumour enlarged it first produced pressure on the lateral column of the same side, the first symptom being that the patient complained of "jumping" of the leg at night. Next, the leg was inclined to give way at times on walking—probably due to reflex spasm. Then the leg tended to drag until finally some degree of paresis was evident. Changes in the abdominal reflex of the affected side occurred very early: at first it was more easily exhausted than that on the opposite side, and later became reduced, with a corresponding increase in the deep reflexes of the leg of the same side. At this stage the plantar reflex might be doubtful or indefinite. He had followed several cases from the earliest manifestations, and motor weakness invariably occurred before any sensory changes developed. The first sensory sign was blunting to pain, heat, and cold in the opposite leg reaching up to within three or four segments of the lesion. These three or four segments represented the space occupied by the sensory fibres in crossing from one side to the other. It was thus seen that the signs tended towards a Brown-Sequard symptomatology.

As regards Pott's disease, the paraplegia had to be watched carefully. If the paraplegia was of the flaccid

variety and was not recovering, the case should be operated upon to prevent the spinal cord from becoming permanently damaged Opened abscesses should be swabbed out with strong mercury perchloride solution In cases of tuberculous pachymeningitis, root pains invariably occurred on movement, and often muscular spinal rigidity, the tissues might also feel boggy on palpation The old test of running a hot sponge up the back was sometimes very useful

The most rapidly fatal cases of compression paraplegia were those due to sarcoma Secondary growths from the kidneys and the suprarenal gland had been more frequent at the National Hospital, Queen Square, as a cause of compression paraplegia than those from carcinoma of the stomach or the rectum A further point in diagnosis was that in cases of chronic leptomeningitis there might be a complaint of abdominal tightness with no objective sensory signs whatever In all compression paraplegias sphincter involvement did not occur until there were signs of bilateral pressure, in cases of leptomeningitis sphincter trouble often developed early

DR C WORSTER-DROUGHT (London) dealt with the practical difficulties that arose in the differential diagnosis of lesions involving the lower cervical and upper dorsal regions of the spinal cord, more especially between (1) compression of the cord, by pachymeningitis or tumour, and syringomyelia with local undissociated anæsthesia and "central" pain, (2) intramedullary tumour and syringomyelia with Brown-Séquard syndrome, (3) early compression paraplegia without sensory changes and a pure spinal type of disseminated sclerosis

(1) *Compression of the Spinal Cord (Pachymeningitis or Tumour) and Syringomyelia with Local Undissociated Anæsthesia and "Central" Pain*—With regard to the differential diagnosis between these two conditions, he had met with the case of a young man who came complaining of weakness in the arms and legs and severe pain radiating from the base of the neck down the arms On examination the patient showed considerable spasticity and loss of power in the upper limbs with bilateral atrophy of the muscles of the shoulder girdle, spastic paraplegia with diminished abdominal reflexes, increased knee- and ankle-jerks, and a bilateral extensor plantar reflex, bilateral, though asymmetrical, loss of cutaneous sensibility of root type to all forms of stimuli (light touch, pain, and thermal) over an area extending across the shoulders and base of the neck, the upper part of the chest, and down the arms—comprising an area supplied from the fifth cervical to the second dorsal spinal segments There was no loss of sensation elsewhere The patient also complained of intense pain radiating from the neck across the shoulders to the front of the chest and down the inner side of both arms On lumbar puncture was obtained only a small quantity of cerebro-spinal fluid, which showed a normal cell count, increased protein content, and a negative Wassermann reaction From x-ray examination, the report stated that "the third and fourth dorsal vertebræ appear to be diseased" Lipiodol had not then been introduced, in any case, Dr Worster-Drought doubted the advisability of using lipiodol when a lesion extended so high in the cervical region, and, as events proved, it would have been of no help Such a clinical picture rendered it extremely probable that a lesion was compressing the spinal cord and involving the anterior and posterior spinal nerve roots It was decided, therefore, to give the patient the chance of benefit offered by operation At the laminectomy performed by Sir Charles Ballance, a large syringomyelia was found involving the area indicated, this was merely incised in the mid-line and the fluid it contained allowed to escape The case, therefore, was one of syringomyelia with the rather unusual phenomenon of "central" pain, believed to be due to the distension of the central canal of the cord The character of the sensory changes and the absence of any dissociated anæsthesia at this stage were noteworthy features (At a later stage, however, the patient developed dissociated anæsthesia in the legs) In view of the large size of the syringomyelia and the small amount of cerebro-spinal fluid obtained at lumbar puncture, the increased protein content was not surprising Another interesting fact was the remarkable improvement in the "central" pain that followed operation, which pain, incidentally, had never recurred The case, apart from its other interesting features, illustrated a difficulty that sometimes arose, and Dr Worster-Drought considered it preferable to operate on three cases of syringomyelia rather than allow a curable case of compression paraplegia to remain unrelieved

(2) *Intramedullary Tumour and Syringomyelia with Brown-Séquard Syndrome*—When a syringomyelia involved mainly one-half the transverse diameter of the spinal cord, the differential diagnosis between these two conditions was extremely difficult, as the physical signs might be identical, and the cerebro-spinal fluid examination and the injection of lipiodol were of no assistance In a case that Dr Worster Drought saw in 1915 this difficulty arose The patient—a woman, aged 25—complained of weakness in the right hand and right foot, with no pain whatever On examination there was weakness and wasting of the intrinsic muscles of both hands, which was more advanced in the right hand than the left, spastic weakness of the legs (right more marked), with right knee- and ankle-jerks greater than the left, and right extensor plantar reflex, left abdominal reflex greater than right, loss of cutaneous sensation to all forms of stimulus over the ulnar distribution of both hands, with absence of pain and thermal cutaneous sense over the left leg and mainly the left side of the trunk, extending upwards to just below the clavicle There was no spinal rigidity or tenderness Syringomyelia appeared to be the probable diagnosis As she was becoming rapidly worse, however, she was admitted to the National Hospital and operated upon by Mr Armour, who successfully removed an intramedullary tumour from the lower cervical region The patient made an excellent recovery, and three years later wrote to say that "she still had the full use of all her limbs, and was able to do her own washing and look after the children" At the present time Dr Worster-Drought had under his care a case of intramedullary lesion, in which it was doubtful whether the condition was one of syringomyelia or intramedullary tumour It was that of a young man, aged 21, who showed a right-sided increase of all deep reflexes, absent abdominal reflexes, right ankle clonus, and right extensor plantar reflex (left indefinite), atrophy of the intrinsic muscles of the right hand, with left-sided cutaneous anæsthesia to pain and thermal stimuli (light touch being everywhere normal) involving the left leg and extending up the trunk to the level of the fourth rib

(3) *Early Compression Paraplegia without Sensory Changes and the Spinal Type of Disseminated Sclerosis*—The difficulty of distinguishing between these two conditions frequently arose The spinal type of disseminated sclerosis—with spastic paraplegia and possibly some degree of unequal muscular weakness in the arms, with no cranial nerve or speech abnormality—was well known, and one seldom found any sensory change beyond the occasional impairment of postural sense, at the same time, all had agreed that in compression paraplegia disturbances of sensation were very late in their appearance The presence even of nystagmus would not favour disseminated sclerosis, for as Dr Fearing mentioned, it had been described in association with lesions of the cervical part of the spinal cord Also, a negative x-ray examination would be reported in disseminated sclerosis and in many cases of compression paraplegia, lipiodol might be of assistance, but again arose the question of the very doubtful advisability of using the substance in lesions of the cervical portion of the cord The cerebro-spinal fluid examination—especially the colloidal gold reaction—might be of considerable help A large increase in protein content would suggest compression paraplegia, but it had to be borne in mind that a slight increase was often found in disseminated sclerosis A positive colloidal gold reaction (with negative Wassermann and a normal cell-count) would favour disseminated sclerosis, in his (Dr Worster-Drought's) experience the colloidal gold curve in the spinal type of disseminated sclerosis was far more often "luetic" than "pretic" From a series of colloidal gold reactions in many cerebro-spinal fluids which he had investigated in conjunction with Drs C Lovell, Roche Lynch, and H J B Fry, it was found that the "pretic" type of curve was usually found in disseminated

sclerosis only when there was evidence of cerebral or cranial nerve involvement the vast majority of cases of the spinal type yielded a curve of the "luetic" type In a case of lesion of the cervical part of the spinal cord met with last year, the diagnosis lay between compression paraplegia and the spinal type of disseminated sclerosis There were no signs of brain changes and the X ray examination was negative The cerebro-spinal fluid (easily obtained in quantity) showed a normal cell count, slightly increased protein content negative Wassermann reaction and a positive colloidal gold reaction with a "luetic" type of curve The subsequent history of the case confirmed the diagnosis of disseminated sclerosis Dr Worster Drought had seen a complete From's syndrome—with xanthochromia and spontaneous massive coagulation—most frequently in connexion with cerebro-spinal fever, especially in cases of complete paraplegia following immediately upon the acute attack It also occurred in this disease apart from paraplegia In his experience From's syndrome was decidedly rare in other forms of compression paraplegia although an increased protein content with no change in the cell-count ('dissociation albuminocytologique') was relatively common

Puncture of the Dorsal and Cervical Theca—With regard to Dr Hildred Carlill's suggestion of puncturing the theca in the dorsal region for the injection of lipiodol Dr Worster Drought considered that more risk was attached to such an operation than to puncture of the cisterna magna Many individuals were devoid of a continuous posterior sub-arachnoid space in the dorsal region the septum posticum being absent and the dura arachnoid adhering directly to the posterior aspect of the spinal cord Lusk in dissections of the spinal meninges in eleven subjects had found that of the eleven only three had pre cut a complete posterior sub-arachnoid space extending throughout the dorsal region into the cervical region In the other eight cases he had found adhesions between the dura arachnoid and the posterior aspect of the cord at some situations between the cervical and the dorsal region In three of these cases medullaris and the cervical region in three or these cases the dura arachnoid was adherent to the entire posterior surface of the spinal cord from the level of the conus medullaris to the cervical region Consequently in puncturing the dorsal theca there was always the risk of inserting the needle directly into the spinal cord The only untoward incident he had seen follow puncture of the cisterna magna—apart from headache and occasional vomiting—was a unilateral and intense hyperaesthesia of the face This was possibly of physiological interest as it might be due to a slight trauma (by the point of the needle) to the tuberculum Rolandi at the side of the medulla—where the sensory spinal root of the trigeminal nerves comes to the surface—with consequent irritation In the case in question the puncture was performed by a zealous house physician and the hyperaesthesia persisted for about a week—preventing the patient's shaving—and then entirely disappeared

THE QUANTITATIVE OBSERVATION OF KERNIG'S SIGN BY A WHEEL GONIOMETER

BY

FRANK C EVE M D F R C P

Physician Royal Infirmary and Victoria Hospital for Children Hull

No one will dispute the usefulness of Kernig's sign especially in suspected meningitis By the following method its usefulness I think, is considerably increased The trouble with Kernig's sign is that the clinician is often in doubt whether to consider it present or absent For this there are two reasons (1) Doubt as to the force we should use in flexing the leg on the trunk, for this varies with the muscles and age of the patient (2) Variations due to the case of the patient for the angle at which Kernig's sign begins to be positive is clearly very different for a baby who can suck his own toe and a stocky middle-aged man who is far from being able to do so But if we can measure Kernig's sign from day to day in a case of doubtful meningitis and find that it is slowly increasing, then we have no doubt that it is (and was) present Also, we can measure its gradual dwindling in convalescence

How then are we to measure Kernig's sign We need not only a handy goniometer* [demonstrated], but also a method or deciding on the angle of Kernig's sign which shall be independent of the force used The method which I have found reliable during the last four years is this The patient lies flat on his back on the bed horizontal The doctor lifts the leg off the bed with the palm of his hand behind the calf just below the middle of the tibia The other hand steadies the leg just above the knee but exerts no pressure As the leg is raised from the bed a critical angle is reached when the knee bends automatically—presumably to ease the stretching of the sciatic nerve caused by flexion of the hip When you are satisfied that this critical angle (at which knee is flaccid and that this critical angle (at which knee flexion just occurs) is constant you measure the angle with the goniometer, it should be about 90 degrees In meningitis it may be far less perhaps 45 degrees

The goniometer consists of a spindle acting as a pivot both for a yard of string and for a wheel graduated in degree The wheel is weighted so that the zero mark always floats to the top For this latter device there are two reasons (1) only one angle need be read (instead of two and subtracting) (2) the instrument need not be buttoned into the bedclothes to the actual hip-joint but can be applied anywhere along the femur The string is then stretched along the leg to the external malleolus while an assistant holds the leg up in the air at the critical angle which has already been determined Read off the graduation on the rim of the wheel where the string intersects it This is the angle of Kernig's sign The goniometer is then simpler to use than to describe my house physicians have no difficulty with it This instrument is also useful for measuring improvement in the flexion of stiff joints or limbs as in compensation cases also in sciatica

In sciatica I have observed that whilst the patient slowly rises from lying to sitting the knee of the affected limb flexes sooner than the sound one This is another way of eliciting my variant of Kernig's sign

SECTION OF PATHOLOGY AND BACTERIOLOGY

Professor C H BROWNING M D, President

CRITERIA OF TRANSMISSION AND CULTIVATION OF ENCEPHALITIS AND ALLIED VIRUSES

BY

J E McCARTNEY M D, D Sc

Lecturer on Bacteriology in the University of Edinburgh

DURING the past few years a considerable amount of work has been done on the experimental transmission of diseases of the central nervous system to animals particularly with regard to encephalitis lethargica Widely different results have been claimed by different workers in their attempts to transmit this disease to rabbits by the inoculation of human material Loewe Hirschfeld and Strauss assert that the disease can be transmitted to rabbit The criterion of infection being the finding of certain brain lesions in the inoculated animals on micro-scopical examination The latter state that the changes consist of a marked meningitis with an infiltration of mononuclear leucocytes The small blood vessels in the cortex and in the basal ganglia show a perivascular infiltration with mononuclear cells and there may be areas of mononuclear infiltration surrounding a zone of necrosis These lesions are stated to be similar to those found in the human brain in encephalitis lethargica and to be diagnostic of the experimental disease Moreover they have claimed the isolation of a micro-organism which they regard as the etiological agent of encephalitis lethargica and that when cultures are inoculated intracerebrally in rabbits lesions similar to the above are found Based on the e results they assert that the culture causes encephalitis lethargica These results have been confirmed by Thillmer who regards the presence of brain lesions as diagnostic of the experimental disease Kling Davide,

* This instrument is being made by Down Bros

and Liljenquist[3] have also claimed that the virus of encephalitis lethargica can be transmitted to rabbits In their experiments intracerebral inoculation of human material produced no observable symptoms, and the animals died many months after the injection Sections of the brains revealed perivascular and meningeal infiltration with mononuclear cells, and from these results the authors assert that the transmission of encephalitis virus to the rabbit has been accomplished These authors point out that not all rabbits are susceptible to the disease, but that only 50 to 60 per cent of the inoculated rabbits reveal these cerebral changes McIntosh[4] also regards the finding of brain lesions in the rabbit as evidence of transmission of encephalitis virus It should also be noted that Reisoner,[5] Plaut and Mulzer,[6] working with experimental syphilis in the rabbit, assumed the presence of perivascular infiltration in the brains of the inoculated animals to be evidence of cerebral syphilis On the other hand, other workers—Levaditi,[7] Doerr,[8] Flexner[9]—have shown that the so-called encephalitis virus produces definite and characteristic symptoms in the rabbit After a short incubation period there is an elevation of temperature (up to 109° F), retention of urine, gnashing of teeth, uncontrolled wild muscular movements, paralysis and convulsions, and finally termination in death within seven days These observers regard the so-called virus of encephalitis as being closely related to if not identical with, the virus of febrile herpes Kling, on the other hand, using the presence of brain lesions as the criterion of encephalitis infection of the rabbit, is unable to show any such relationship It was pointed out by Bull,[10] confirmed later by Olivet,[11] and emphasized by Flexner,[9] that apparently normal uninoculated rabbits may show, on examination of the brain, areas of perivascular and meningeal infiltration with mononuclear cells

At Dr Flexner's request I carried out an investigation as to the presence and extent of the brain lesions in laboratory rabbits in the Rockefeller Institute, New York, using a large amount of material that was available at the time[12] In addition to the ordinary stock uninoculated rabbits, brain tissue was obtained from stock rabbits suffering from snuffles and other intercurrent infections such as pneumonia and subcutaneous abscesses, from rabbits injected intratesticularly with *Spironema pallidum*, and from animals inoculated in the testis with a transplantable tumour Four types of animals were thus studied It is to be noted that none of the experimental animals (for the material from which I am indebted to Drs Wade H Brown and Louise Pearce) had been inoculated intracerebrally The total number of rabbit brains examined was 372 The brains were removed whole, and fixed in either 10 per cent formalin or in Zenker's fluid Complete transverse sections of the cerebrum, and also, in most of the cases, portions of fore brain, mid brain, and medulla, were examined The sections were stained with hæmatoxylin and eosin, and, in addition, by Giemsa's method It is probable that this extended and complete examination of the brain accounts for the high percentage of lesions detected

Results of the Microscopical Examination of Brain Material from 372 Rabbits

The lesions found in the brains of these rabbits are characterized chiefly by an infiltration with mononuclear cells, and also in some cases by areas of peculiar localized necrosis The infiltrative changes may be divided, according to the location, into four types (1) perivascular, (2) meningeal, (3) in the cerebral substance, and (4) under the ependyma of the lateral ventricles It is to be noted that several or all of these types may be present together, and, in addition, localized necrosis The perivascular, meningeal, and cerebral types are usually found together, but any of the types may predominate The infiltrating cells are small, round, deeply staining, and mononuclear

1 *Perivascular Lesions*—This is the commonest lesion noted, and is often very striking The infiltration with the mononuclear cells may vary from a single layer to a thick dense sheath, and the cells may also be found in the so-called Virchow-Robin spaces

2 *Meningeal Lesions*—Involvement of the meninges is not quite as frequent as the perivascular, and consists of an infiltration into the pia-arachnoid with mononuclear cells In marked cases there is a broad band of cells on the surface of the brain from which finger-like masses, surrounding the blood vessels, penetrate the brain tissue

3 *Lesions in the Cerebral Substance*—These occur, in order of frequency, intermediate between the perivascular and meningeal lesions, being usually associated with the former There may be a diffuse infiltration with mononuclear cells, or, more often, focal aggregations of cells distributed irregularly

4 *Lesions under the Ependyma*—This is the least common lesion, and may only be found in the fore brain

Lesions with Necrosis—In 15 per cent of the total number of brains examined, localized areas of necrosis were noticed in addition to the infiltrative changes This lesion consists of a necrotic centre surrounded by epithelioid cells, around which is a layer of mononuclear cells The neighbouring blood vessels show perivascular infiltration In Giemsa preparations the necrotic centre sometimes shows protozoan-like structures, named by Levaditi *Encephalitozoon canicoli*, and regarded by some observers as the etiological agent of the lesions

Distribution and Incidence of Lesions

Source of Rabbits	No of Rabbits Examined	Percentage showing Brain Lesions
Transplantable tumour	146	50
Experimental syphilis	82	40
Normal uninoculated stock	52	60
Natural miscellaneous diseases (excluding snuffles)	50	70
Snuffles	42	76
Totals	372	55

From this table it is seen that the lesions of meningo-encephalitis of the types described were present in more than half (55 per cent) of the total number of 372 rabbits examined, and of which none was inoculated intracerebrally The lowest incidence was in the syphilis rabbits—40 per cent , tumour rabbits showed 50 per cent , and apparently healthy stock 60 per cent In the animals suffering from natural miscellaneous diseases such as pneumonia, septicæmia, and subcutaneous abscesses, 70 per cent showed lesions, while in the snuffles group 76 per cent were affected The areas of necrosis were present in 15 per cent of the total

It is thus seen that about one-half of the 372 rabbits showed lesions of meningo-encephalitis, and the recognition of the occurrence of such lesions is of the greatest importance in the interpretation of experimental results based purely on the histological examination of brain tissue The conflicting results of various observers on the transmissibility of encephalitis lethargica to the rabbit is due to the lack of recognition of spontaneous or accidental lesions in this experimental animal The pathological changes regarded by Loewe and Strauss as being diagnostic of experimental encephalitis lethargica in the rabbit, and which are described and illustrated in their various papers, appear to be identical with the lesions found in uninoculated rabbits and in rabbits not injected intracerebrally Therefore their conclusions, which are based solely on the histological examination of the brains of experimental animals, cannot be accepted The work of Kling and his associates is open to similar criticism A comparison of the photographic reproductions of what Kling and his co-workers regard as specific encephalitic changes, with the material here described, shows the lesions to be identical The peculiar necrotic areas which are stated by Kling to be pathognomonic of experimental encephalitis were found in 15 per cent of the rabbits supposedly normal or not inoculated with encephalitis material Kling also states that only 50 to 60 per cent of his inoculated rabbits were susceptible—that is, in which lesions were found These figures coincide with the present finding that 55 per cent of rabbits not inoculated with encephalitis material show similar pathological cerebral changes

Cultivation Tests with Encephalitis and Herpes Virus

The second part of the paper relates to cultivation tests with the so-called virus of encephalitis lethargica and of herpes febrilis.

In the following experiments two strains of the so-called encephalitis virus (Beckley and Leydig strains) and one strain of herpes virus (Hull strain) obtained from Dr. Simon Flexner were employed.

The criteria for establishing the experimental transmission of the so-called encephalitis virus to the rabbit are as follows:

1. *The Period of Incubation*.—This is usually from two to five days after injection, but with weak or attenuated strains periods up to twelve days may elapse before clinical symptoms are noticed.

2. *Symptoms*.—The first symptoms to be noted are elevation of temperature and retention of urine. The former is usually 105° to 106° F., but often reaches 107°, occasionally 108° F. This temperature is sustained throughout the course of the disease until just before death, when it is rapidly lowered and may become subnormal. The retention of urine is a very frequent sign, and may be demonstrated very slight pressure. The animal round the loins and using gently crisping the animal. Then as much as 300 c.cm. of urine may be expressed from the animal. The fever may continue for twenty-four to forty-eight hours, when general symptoms relative to involvement of the central nervous system become evident. The animal is hypersensitive, makes wild dashing movements, which, owing to disturbance of vision are often terminated by the animal hitting the wall or other obstacles. After a few moments of quiescence the animal bends back its head, lifts one or both fore paws off the ground, then stands up on its hind legs and finally falls backwards, forwards, or sideways. Sometimes the animal runs in circles, at other times it may rush forward until it is stopped by some obstacle. Salivation is very frequently observed. The saliva runs freely from the mouth, wetting the fur around the jaws and neck. Grinding or gnashing of the teeth is also very frequently noted. A few hours later the animal becomes weak and paretic, and lies on its side. At this stage the temperature is lowered, and the breathing laboured. Convulsive attack follows, in which the animal dies.

3. *Post mortem*.—The viscera are found to be normal. Care must be taken to exclude pneumonia, rabbit septicæmia, or other affections. The brain usually shows slight congestion. There is no apparent meningitis present.

Cultures made from heart blood, lungs, and brain show no growth in ordinary media, thereby eliminating septicæmia, pneumonia, or meningitis, or other known affections as the cause of death.

4. *Transmissibility*.—The virus from rabbit to rabbit by means of intracerebral injections of suspensions of affected brain can be effected indefinitely.

Cultivation Tests in Smith-Noguchi Medium

The animal was killed in extremis and the brain immediately removed with strict aseptic precautions. The cerebrum was carefully cut into portions about 1 cm. square, and such fragments were added to the Smith-Noguchi medium (fresh sterile rabbit kidney with ascitic fluid, and covered by a layer of vaseline) and incubated at 37.5° C. Cultures were examined at frequent intervals, and films stained by polychrome methylene blue, Gram's and Giemsa's methods. Numerous experiments were done using the three strains of viruses and also employing variations of the Smith-Noguchi technique, but in no instance were any micro-organisms detected. The results of Loewe and Strauss, who claimed to have cultivated minute "globoid" bodies, could not be confirmed. Since no living multiplying agent could be detected, the viability of the viruses in various media was determined in the hope of finding a suitable pabulum for the multiplication of the inoculant.

Experiments using Collodion Sacs

The so-called encephalitis and herpes viruses do not survive for five days when placed with either Ringer's solution or broth, in collodion sacs [illegible] abdominally in the

Survival of the Virus in Anaerobic and Aerobic Media

It is Loewe and Strauss state, the virus of encephalitis lethargica multiplies in Smith-Noguchi medium then *pari passu* the culture should remain active for a long period of time. It was thought that information as to the time the virus can survive in this medium would indicate whether it had merely survived, or had died, or even had multiplied within the cultures, and would thus control the above-mentioned negative result. The viability of the virus was tested by inoculating rabbits intracerebrally with (*a*) the brain fragment itself and (*b*) the fluid surrounding the tissue. In this way the presence of the virus in the fluid medium could be determined and also the length of time the virus remained active in the brain at the height of the disease was inoculated into a series of Smith-Noguchi tubes and incubated at 37.5° C. At intervals of two days a tube was examined for the presence of the virus. The ascitic fluid was poured off, centrifuged at low speed to deposit particles of brain, and a uniform deposit into a young (1,000 gram) rabbit. The piece of brain tissue in the culture was weighed in a sterile capsule and a 10 per cent. emulsion made in normal saline. 0.25 c.cm. of this emulsion being inoculated intracerebrally into a young rabbit. For control similar pieces of brain were incubated in ordinary 1 per cent. glucose broth and inoculated aerobically at 37.5° C. The supernatant broth and fragment of brain were treated and inoculated in a similar manner to the Smith-Noguchi cultures. The experiment was repeated several times with each of the three strains of virus.

Result.—After two days' incubation the centrifuged ascitic fluid from the Smith-Noguchi medium was non-infective, showing that the virus had not multiplied or even diffused into the surrounding medium. The virus, however, was still viable in the brain itself up to the sixth and occasionally the eighth day. The larger the piece of brain the longer the survival. On the other hand, when incubated in glucose broth under aerobic conditions the virus was present in the surrounding fluid, the test dose of 0.25 c.cm. being as active as the fresh virus. Moreover the brain fragments were still infective after twelve days' incubation. The experiments were repeated, the virus being added to these media in the form of ground up emulsion of brain tissue. Similar results were obtained. Virus could not be recovered from the Smith-Noguchi tubes after two days' incubation, showing that it had either been killed or rendered inactive while in aerobic broth the virus was still active after four days' incubation. These results show that Smith-Noguchi medium is not favourable even as the survival much less for the multiplication of the encephalitic herpetic viruses. On the other hand, aerobic broth is much less destructive to the virus which is able to diffuse into the medium and remain alive for six days. Attempts were made to determine what relation the oxygen tension and hydrogen concentration bore to the destruction of the viruses in Smith-Noguchi medium or their survival in aerobic broth. Changes in the oxygen tension and variations of the *p*H between 7.4 and 6.2 exerted no appreciable effect.

Summary

Summarizing therefore normal stock rabbits reveal in a high percentage of cases lesions identical with those described by other workers as evidence of the experimental transmission of encephalitis lethargica.

The results of experimental work in which the histological findings in the brain of the rabbit have been taken as the criterion for a positive transmission of the virus of encephalitis lethargica to that animal cannot be accepted. Contrary to the results of Loewe and Strauss, who claim to have cultivated the virus of encephalitis lethargica by the Smith-Noguchi technique, this medium is not favourable even for the survival, much less for the multiplication of the virus. Aerobic broth is a better medium for maintaining the activity of the virus. These results fail to uphold not only the cultural [illegible]

of Loewe and Strauss, but also that of other workers to identify the encephalitis virus with certain ordinary bacteria

Using an accurate technique, the so-called virus of encephalitis lethargica can be passed from rabbit to rabbit under conditions in which no visible organisms can be detected microscopically or made to grow in culture media

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

HYDRAEMIC NEPHRITIS

THE following instance of this condition, which came under my care rather more than two years ago, was quite the most severe that I can recall. The case notes exemplify the utility, for clinical purposes, of the classification of nephritis as hydraemic or azotaemic, and may prove of use as indicating the line of treatment to be adopted in cases of the former type.

In March, 1922, Mrs. S., aged 46, who had previously been perfectly healthy, sent for me because oedema of the legs had developed. During the autumn of 1921 she had endured the strain of nursing her husband in a severe illness until his death in December. In January, 1922, she was passing large amounts of very clear urine, chiefly during the night and towards early morning. In February she began to pass water almost hourly, very little at a time, and could hardly retain it. In March the amount noticeably lessened, and the legs began to swell. Very soon afterwards she was acutely dropsical in the legs, arms, face, and conjunctivae, there was severe *oedema of the abdominal* wall and lumbo-sacral regions, and ascites and hydrothorax. She suffered from cough and a choking feeling, and her body was so unwieldy and increased so much in size that she could hardly move in bed. The blood pressure was normal, the systolic pressure being 120 and the diastolic 80. The pulse was quiet and regular, the heart healthy, and the ocular fundi normal. The urine averaged 8 to 12 oz. in the twenty-four hours; it was intensely albuminous, so that, even when diluted by an equal part of water, the albumin filled an Esbach tube to the top mark. The urea concentration test and the diastasic test showed that *the kidneys were dealing with nitrogenous substances normally. The symptoms were therefore due to chloride retention.*

Light diet and diuretics of various kinds, including digitalis, *potassium acetate*, caffeine diuretin, nux vomica, strophanthus, and others, had some effect, since the urine excreted in twenty-four hours rose to 20-30 oz., and by May 15th was 40 oz. The latter figure was reached, however, after all medicines had been stopped for two days. From the beginning of May the protein content of the diet was increased, and fish, eggs, tripe, chicken, bread, biscuits, butter, fruit, tea, and milk were given. During all this time no effect was produced on the general anasarca. No dangerous symptoms developed, but she remained immensely unwieldy and uncomfortable. On May 25th 225 grams of urea were given twice daily, and continued for three weeks; it was then stopped, no appreciable benefit having occurred. The diet was now practically saltless, the bread being specially prepared and other means taken to secure this. At the beginning of her illness, curiously enough, she had a great craving for salt which of course was not gratified. Throughout the illness attention was paid to the bowels, but *even fairly free purgation had no effect.* In short, no real improvement had been obtained by any of the means taken. As the anasarca remained intense, affecting especially *the abdomen and back, the question of pressure on the* kidneys by ascitic fluid and of renal and perineal oedema arose. The urine in June averaged 8 to 12 oz. in the twenty-four hours.

On June 26th I inserted a Southey tube into the subcutaneous tissues on the outer side of each ankle, and kept them in until June 29th. In that time there drained away 23 pints 9 oz. of fluid, and there was a decided diminution of the anasarca. On July 10th I inserted one Southey tube high up on the outer aspect of one thigh and removed it on July 12th, 9 pints 4 oz. of fluid having drained away. Diuretics were then resumed. The patient was easier and was able to sit up in bed. The urine, which had averaged 20 to 30 oz. in the twenty-four hours, rose on July 20th and 21st to 42 and 58 oz., and on July 23rd and 24th to 60 and 74 oz. respectively. Dietetic and medicinal treatment was maintained as before, and her progress was now *steadily good.* By September a mere trace of oedema remained with only slight albuminuria, and by the end of the year she was practically well and performing all her household duties. The cardio-vascular and other systems remained normal. From time to time in 1923 I examined the urine, as also recently, and found it to be perfectly normal in all respects, and the patient in sound health and vigorous.

The dietetic treatment in this case was very different from what it was, say, thirty years ago, when many patients were "drowned" by excess of fluids. No treatment did the present patient any good until the fluid in the tissues was mechanically drained away. I regret that I did *not tap the legs sooner, for recovery began very quickly* after the 32½ pints of fluid were withdrawn. No trouble occurred at the points of insertion of the tubes. The tubes were boiled, inserted through iodized skin, and the whole area was covered with sterile gauze and collodion.

Glasgow R. O. ADAMSON, M.D.

PERFORATED GASTRIC ULCER

THE following account of a somewhat unusual case—namely, perforation of a gastric ulcer, with general peritonitis, in a boy aged 16, with no past history suggesting gastric trouble, and with atypical physical signs—may be of sufficient interest to merit publication.

The patient gave a two days' history of pain extending transversely across the abdomen at the level of the umbilicus. This had not prevented him from working until noon of the day of admission to hospital when the pain had become more severe and he had vomited for the first time. There was no past history of abdominal pain. The face was flushed and the tongue slightly furred, temperature 99°, pulse rate 92. The abdomen did not move well on respiration, the point of *maximum pain was slightly* to the left of the umbilicus. The upper halves of *both recti and* the lower half of the right rectus were slightly rigid. There was no epigastric tenderness, both iliac fossae were *tender, especially the left. There was tenderness on rectal examination, greater on* the left side.

A provisional diagnosis of acute appendicitis was made and I accordingly communicated with Mr. L. E. Barrington-Ward, who requested me to operate. Assisted by Mr. H. Sandeman Allen I opened the abdomen by a right paramedian incision below the umbilicus. General peritonitis was discovered, the peritoneal cavity being full of greenish coloured fluid. Beyond sharing in the general peritoneal injection, the appendix was normal. The incision was accordingly continued upwards and the stomach examined. A small perforation, *surrounded* by an extensive indurated area, was found on the anterior surface of the stomach just below the junction of the middle and right thirds of the lesser curvature. This was invaginated and a piece of omentum stitched over the invaginated area. The wound was then closed, with drainage of the stomach area and of the pelvis. The patient has now made an uninterrupted recovery.

I am indebted to Mr. L. E. Barrington-Ward for permission to publish this case.

A. C. MACONIE, M.B., B.S. *Lond.*

Royal Northern Hospital, Holloway.

SUBMUCOUS LIPOMA OF CAECUM

THE following case seems worthy of record.

Mrs. Y., aged 61, was admitted to the Bedford County Hospital on May 31st, 1924, as a case of appendicitis. The history was that six months previously she had an attack of *diarrhoea*, followed by attacks of abdominal pain and severe constipation. One week before admission she had severe colicky pain and vomiting.

On admission she had definite tenderness and rigidity in the right lower quadrant of the abdomen. Her temperature was 99° F. and pulse rate 90. Without delay the abdomen was opened by right paracentral incision. The appendix was thickened, but not inflamed. The caecum, which felt as if it contained a mass of worms, was opened by an anterior incision and a submucous lipoma found projecting on the posterior wall. The mucous membrane *was incised over the mass* which was then shelled out. The mucous membrane was sutured with fine chromic gut and the caecum closed with a double line of sutures. Recovery was *without incident* and the patient left the hospital on June 18th.

Submucous lipomata of the caecum and colon are very rare. I have seen one previous case, which occurred in a patient of mine, a man aged 44, on whom Sir J. Bland Sutton operated. The case is described in the *Lancet*, vol. i, 1900 (p. 1437). In my case the tumour measured 4 by 2½ inches, and was about one inch in thickness.

British Medical Association

CLINICAL AND SCIENTIFIC PROCEEDINGS

KINGSTON-ON-THAMES DIVISION

At a meeting of the Kingston-on-Thames Division, held at the Surbiton Hospital on November 11th, a paper was read by Mr FREDERICK HOBDAY, C.M.G., honorary veterinary surgeon to the King and President of the Comparative Medicine Section of the Royal Society of Medicine.

Mr Hobday took as his subject the value of collaboration between the medical and veterinary professions for the eradication of anthrax and tuberculosis using rabies as an example of the value of stamping out a disease from animals, and so abolishing hydrophobia in man. Glanders, similarly, should soon be relegated to the category of diseases which students could only study from textbook descriptions, twenty-five years ago nearly 2,000 horses were destroyed for this disease in the London area, in the present year there had been only one horse destroyed in the whole of Great Britain. Both rabies and glanders were transmitted to man primarily through the agency of an infected animal, and the disease was diagnosable and preventable in these animals only by the trained veterinary surgeon. So long as co-operation between the medical and veterinary professions continued, and legal regulations were loyally observed, neither glanders nor rabies would regain a footing in this country as diseases affecting man.

Passing to anthrax, the lecturer remarked that this also was a disease of animal origin, to be dealt with in the first instance by the veterinary surgeon. The difficulties were greater in this case, since ruminants which were the chief source of the disease, furnished the world with many more useful products than did the horse and dog. Food, hides, hair, wool, and bone manure for land fertilization, were all essential and in everyday use. Moreover the longevity of anthrax spores and vitality of the bacilli rendered it difficult to ensure the safety of land where anthrax carcasses had been buried. Sir John Moore, in a recent paper before the Royal Society of Medicine had illustrated this point from his experience in India, where it had been found that ground so infected could never be used for grazing. The compulsory destruction of such carcases by burning now in force in this country appeared to be the only safe way of dealing with the difficulty. At the International Labour Congress, held in Geneva in 1921 an International Committee had been appointed to consider the disinfection of wool and hairs infected with anthrax, the effective methods of preventing infection among flocks, and the possibilities of dealing with infection by anthrax from hides, skins, and other material. Statistics indicated that infection was often derived from foodstuffs such as cotton-seed and linseed cake, but no way had yet been devised to disinfect these thoroughly without destroying their nutritive properties. With regard to wool and hair, the experimental disinfection station at Liverpool, which commenced work in July, 1921, and through which all such products entering this country had to pass, had proved very successful. The formaldehyde treatment to which anthrax infected wool was subjected there had reduced the danger of infecting the human workers. This station, erected at a cost of over £100,000, could turn out some six million pounds of clean wool annually, and was equally applicable for the disinfection of horsehair, so that a very great improvement had been made during the past two or three years in diminishing the risk of what was once considered an invariably fatal disease. Sclavo's serum—the sheet-anchor in human treatment—was unreliable for animals, and in horses and cattle the disease still remained one of the most rapidly fatal of all microbic diseases. When it could be eradicated from the category of animal infection its abolition as a disease affecting man would automatically follow—another instance of the necessity for close co-operation between the medical and veterinary professions.

In regard to tuberculosis, Mr Hobday pointed out that authoritative statements had assigned no less than 85 per cent. of cases of tuberculous cervical glands in children to a bovine origin, that over 10,000 children died annually owing to tuberculous milk, and that there were fully a million tuberculous cattle in Great Britain. At present, with the exception of certain cities, there was practically no veterinary inspection of cows and cowsheds, even when a cow was detected with a tuberculous udder there was no legal compulsion for the slaughter of the animal, which might be transferred to a neighbour or sold in the open market. A resolution pleading for the reintroduction of the Animals Tuberculosis Order, suspended in 1914 had been sent to the Government by the National Veterinary Medical Association and by many of its branches. Under this Order it was compulsory for an animal with a tuberculous udder to be destroyed, compensation being paid to the owner. Although the destruction of every tuberculous cow would be impracticable at the present time for financial reasons, yet the re-establishment of this Order would prevent much disease in children. In a paper read before the Section of Pathology at the Annual Meeting of the British Medical Association at Glasgow in July, 1922 (reported in the JOURNAL of November 18th, 1922, p. 955), Mr Hobday had drawn attention to a new method of immunization of calves introduced by Dr Nathan Raw, the then president of the Tuberculosis Society of Great Britain and Ireland. In the *Veterinary Journal* for November of this year Dr Raw had published details of the results in a large pedigree herd during the past two years, all the calves had been vaccinated and afterwards tested regularly with tuberculin, and had passed successfully, this being in marked contrast to the former experience of the owner concerned, who had previously found reactions to be numerous. Mr Arthur Payne, of Wivelsfield, had also obtained similarly satisfactory results. In 1921, 50 per cent. of a pedigree herd under his care had reacted to the tuberculin test, in 1923, 15 per cent. reacted, in October, 1923, 10 per cent., in April, 1924, 5 per cent., and in October, 1924, there were no reactions. Dr Raw stated that animals so treated were able to resist invasion by the tubercle bacillus. Mr Hobday felt that the combination of Dr Raw's method of immunizing with the reintroduction of the Animals Tuberculosis Order would stamp out tuberculosis in cattle and be of enormous value in counteracting tuberculosis in children.

At the conclusion of the meeting Dr. W. C. CARVER proposed, and Mr. W. M. GOODMAN seconded, the following resolution, which was passed without dissent:

> That the prevalence of tuberculosis in cattle in this country continues to be a serious menace to the health of human beings and that to counteract this danger the reintroduction of the Animals Tuberculosis Order which was suspended in 1914 is urgently needed.

Reports of Societies.

NON-TUBERCULOUS MENINGITIS

A joint meeting of the Sections of Medicine, Otology, Neurology, and Pathology of the Royal Society of Medicine was held on December 10th with the President of the Section of Medicine, Dr ROBERT HUTCHISON, in the chair.

Dr J. H. THOMPSELL, who opened the discussion on the causes, early recognition, and treatment of non-tuberculous meningitis, said that the extensive practice of lumbar puncture during the past twenty-five years had added greatly to their knowledge of the pathology of these conditions. He regarded the cases classed as meningismus in which the symptoms and clinical signs of meningitis were present yet the cerebro-spinal fluid showed no changes as early cases of true meningitis where the defensive mechanism was sufficient to overcome the infection. The same happy result sometimes occurred in cases of frank meningitis, particularly in those of aural origin with purulent cerebro-spinal fluid. There followed the difficulty of separating the severe and dangerous cases of meningitis from those which would recover practically spontaneously. The symptoms and signs of meningitis were those of cerebral disturbance, headache, vomiting, delirium, coma, together with squints, transient palsies or clonuses, and Kernig's and Brudzinski's signs might all occur in the course of an acute non-meningeal infection. Definite changes in the cerebro-spinal fluid in the direction of increase in albumin and cell

content occurred in cases of focal infection in proximity to the meninges as well as in the meningitis of mumps Apart from the tubercle bacillus and meningococcus, which were omitted from the discussion, nearly every known organism had on occasion been responsible for a meningeal infection, the commonest were the streptococcus, pneumococcus, and *B influenzae*, but *B coli communis*, *B typhosus*, the gonococcus and staphylococci, and various forms of streptothrix also occurred *In most cases there was a primary focus of* infection in the ear, nasal sinuses, bones, or viscera, but *the pneumococcal and influenzal forms of meningitis were* generally primary As to treatment, any primary focus discovered should be dealt with surgically, and in the absence of such focus something could be done by the exhibition of a sensitized vaccine or blood transfusion from an immunized donor Cases of mild streptococcal infection often recovered after repeated lumbar puncture alone

SIR WILLIAM MILLIGAN said that meningitis was a frequent complication of septic middle-ear disease, and that 5 to 6 per cent of all cases of meningitis admitted to his hospital were of otitic origin In the early stages of otitic *meningitis there was little to indicate the onset of the* disease beyond a rise of temperature to 101° to 102° F, with perhaps a rigor, later the signs of cerebral pressure became manifest Meningeal infection began in the immediate neighbourhood of the primary focus, hence the impor*tance of performing a radical mastoid operation, even in* acute cases, in order that all the usual paths of infection might be carefully scrutinized, this in itself was often sufficient to ward off an impending meningitis SIR William Milligan considered that three types of otitic meningitis should be differentiated (*a*) the serous with a sterile, though often turbid, cerebro-spinal fluid (meningitis benigna), (*b*) a type in which the cerebro-spinal fluid was rich in cellular contents but showed no visible organisms (meningitis semi-maligna), (*c*) a type similar to type (*b*), but with living organisms present in the fluid (meningitis maligna) An accurate diagnosis of the type of meningitis, upon which the prognosis was dependent, could only be made by an examination of the cerebro-spinal fluid The fluid should, when possible, be obtained from the immediate neighbourhood of the primary focus, since that obtained by lumbar puncture might exhibit less marked changes Cases *of meningitis serosa usually recovered, but the prospects of* recovery in meningitis semi-maligna or maligna (for the latter was usually the *end-result of the former*) depended upon the success obtained in providing sufficient drainage *of the subarachnoid space* and cisternae, as well as the removal of the primary *source of infection* When the symptoms suggested implication of the cisterna pontis the dura in the neighbourhood of infection should be exposed and punctured, and the fluid examined *If* organisms were found in the fluid drainage should be provided by tubes or *strands of gauze In the cases where labyrinthitis* was the primary source translabyrinthine drainage was the operation of election In advanced cases of leptomeningitis the prognosis was extremely grave *Post-mortem* examination showed that the cisternae were invariably infected, and suggested that in the treatment of this condition efforts should be made to drain the cisterna pontis, the cisterna basalis, and the cisterna magna In conclusion, SIR William Milligan urged that operation should be undertaken in all cases of septic meningitis of otitic origin, in the past many lives had been lost by regarding the condition as hopeless, and operation, in consequence, uncalled for

DR C WORSTER-DROUGHT pointed out that syphilitic meningitis, *which might supervene within a few months of* the primary infection, gave rise to similar symptoms and changes *in the cerebro-spinal fluid to those of tuberculous* meningitis, from which it might be distinguished by the *Wassermann reaction and the results of treatment*, since the prognosis in syphilitic meningitis was very good He had seen meningitis connected with the ear, nose, and throat (1) after nasal operations, (2) secondary to intranasal or sinus disease apart from operation, (3) following wounds of the jaws, (4) secondary to suppurative otitis media In one remarkable case of meningitis associated with *B fusiformis* no primary focus was found at the *post-mortem* examination other than pyorrhoea alveolaris He considered the following to be the most valuable signs

1 *Rigidity of the posterior cervical muscles*
2 Kernig's sign
3 The pulse temperature ratio—a comparatively slow pulse associated with high temperature
4 Delirium or stupor with irritability
5 In infants, bulging of the anterior fontanelle

Head retraction he regarded as useless as a sign, and Brudzinski's sign as of less importance than Kernig's No reliance could be placed upon the reflexes for early diagnosis, but intense mental irritability accompanied by stupor was a valuable sign The diagnosis could, of course, only satisfactorily be established by examination of the cerebro spinal fluid Two principles governed the treatment of all forms of non-tuberculous meningitis (1) the establishment of efficient drainage of the meningeal exudate, and (2) the application of a specific immune serum as closely as possible to the inflamed tissues The first could be attained in most cases by repeated lumbar puncture, but in a few cases puncture at a higher level was called for, either in the cervical region, or puncture of the cisterna magna, sphenoidal puncture through the orbit, or puncture *of the lateral ventricles The second principle required the* daily introduction of serum into the subarachnoid space by lumbar puncture, since, if administered intravenously, *the immune serum did not reach the cerebro-spinal fluid in* any appreciable concentration

DR J G GREENFIELD spoke of the difficulties of the pathologist in dealing with the cerebro-spinal fluid obtained from suspected cases of meningitis, since there were a multitude of tests and reactions and only a limited quantity of fluid The problem was to attempt to arrive at a diagnosis and prognosis in two types of case first, those yielding a clear fluid yet exhibiting signs and symptoms of meningitis, and secondly, those in which there was a purulent exudate without signs of the disease, this latter being the more difficult, especially in cases associated with an sinus empyema The prognosis in *the latter type depended* on whether the pus under the dura was localized or not, and could be to some extent gauged by the presence or otherwise of organisms and their nature When a virulent streptococcus was the cause the outlook was very bad, in the case of other organisms it was better He regarded the protein and sugar contents of the fluid as of little *prognostic value*, but the chloride content was of the greatest significance Normally this was about 720 to 770 *mg per* 100 c.cm A figure of 630 to 690 indicated the danger zone, in which the patient might be expected to succumb to *generalized* meningitis, whereas the speaker had never known a patient to die in whom the figure remained within normal limits Craniotomy invalidated this test, which indicated the increased permeability to sugar of the inflamed meninges

MR W M MOLLISON, who discussed the subject of *meningitis of rhinogenic origin*, said that such cases might occur as the result of direct violence at operation, but more often the meningitis was a sequel of some intracranial complication of nasal disease such as pachymeningitis, cerebral abscess, cavernous sinus thrombosis, or osteo-myelitis of the frontal bone Infection might spread from the nose to the meninges (*a*) through gross lesions of the cribriform plate, (*b*) by direct spread or osteo-phlebitis, in which organisms had been traced in the vessels passing *through* bone which might appear to be normal, (*c*) by venous spread *following thrombosis* to the cavernous sinus and duræ viæ (1) the ophthalmic vein, (2) the spheno-palatine vein, (3) the veins from the nose to the superior *longitudinal* sinus, and (4) the diploetic veins, (*d*) by lymphatic spread, probably a fairly frequent route after nasal operations, since it had been shown that lymphatics run with the fibres of the olfactory nerve After a brief consideration of non-operative rhinogenic cases of meningitis, MR Mollison passed to the consideration of the operative cases, and quoted extensively from the literature on the subject Almost every variety of intranasal operation had been responsible for meningitis, operations upon the ethmoid being the most frequent cause Though the prognosis of post-operative meningitis was extremely bad, a few cases of recovery had been reported The speaker himself had

been fortunate in having only one fatal case, and two recoveries. The diagnosis did not differ materially from that of meningitis of otitic origin and the changes in the cerebro-spinal fluid were similar. Treatment was of little avail, particularly in post-operative cases. It therefore behoved a surgeon to take all possible precautions. His own rules were: (1) never to operate when the patient had an acute cold, (2) if possible, to open all sinuses containing pus at one sitting, (3) never to leave plugs in the nose for more than twelve hours, (4) to treat the middle turbinal with care, and (5) to avoid the olfactory sulcus.

Mr W. STUART-LOW, Mr C. I. WEST, Dr D. V. NAVARRO and Dr W. L. C. DICKSON also spoke, and the PRESIDENT commented on the value of the discussion.

SPLANCHNIC ANALGESIA

At a meeting of the Section of Anæsthetics of the Royal Society of Medicine on December 12th, Mr O. S. HILLMAN read a paper on splanchnic analgesia.

Mr Hillman stated that Crile's method of anoci-association, which aimed at cutting off nerve stimuli and sensations by means of local infiltration of the area to be operated upon, had its limitations, and perhaps also its disadvantages. The method to be described was regional splanchnic block, the splanchnic nerves on each side being reached by the posterior route, the needle was inserted below the twelfth rib at the level of the first lumbar vertebra, and at a distance of 7 cm. or four fingerbreadths from the middle line of the spine. The needle was inserted through a wheal in the skin if the patient was conscious, but if not it was pushed in direct, in a forward, inward, and slightly upward direction at an angle of 45 degrees with the median body-plane to a depth of about 9 cm., when it should reach the body of the first lumbar vertebra near its anterior convexity, in front of the intervertebral foramen and behind the splanchnic nerves. After striking the bone, which should be effected with gentleness lest the point of the needle be injured, the needle was withdrawn until its point lay in the subcutaneous tissues, and was reintroduced at a smaller angle to a point 1 cm. deeper than the spot first reached. The syringe was then applied to the needle, and aspiration was attempted in order to ensure that the needle was not in the lumen of an artery or vein. A solution of 1 per cent. novocain was then inserted, and in no case was more than 5 oz. of the solution used. About 1 oz. of solution would be necessary for each side of the body. The peripheral nerves were then dealt with either by paravertebral or by abdominal blocking. It was usually advisable to administer a general anæsthetic, but a minimum would suffice. The advantages of the method were (1) small respiratory excursion, (2) complete anæsthesia, (3) absence of straining when there was traction of sensitive parts, and (4) marked reduction of shock. The disadvantages were: Some twenty minutes was added to the length of the operation and there was a possibility in a lengthy operation that the field block might pass off. The advantages to the patient were that very little general anæsthetic was necessary, shock was reduced to a minimum, respiratory fatigue was abolished, there was no impairment of the general condition of the patient when the effect of the anæsthetic had passed off, there was little danger of respiratory complications following the anæsthetic, and there was usually less post-operative pain. The only disadvantages were occasional flatulent distension of the bowels, and headaches in a few cases as sometimes occurred after spinal injections. Mr Hillman showed photographs of the cadaver to illustrate his technique and a number of pulse and blood pressure tracings. The latter demonstrated the fact that a fall of blood pressure occurred about twenty minutes from the commencement of the injection, and that this effect gradually diminished, so that at the end of the operation the pressure had attained or was rising to the level at which it stood prior to injection. The tracings showed also that the pulse rate did not rise in proportion to the fall of blood pressure, but remained fairly constant. The total number of cases operated upon was 48, of which 26 were for gastrectomy. The mortality was 7 cases, of which 2 had had a partial gastrectomy performed.

Mr R. F. APPERLY then read a paper describing 43 cases of splanchnic analgesia, with a mortality of 5. Of the total operations 17 were gastrectomies, and three of these patients died. He agreed with the previous speaker regarding the advantages and disadvantages of the method. While he considered it preferable that a general anæsthetic should be given in addition to the block anæsthetic, the condition of the patient was sometimes so desperate that a general anæsthetic had to be avoided. In these cases a preliminary injection of morphine gr. 1/4 and scopolamine gr. 1/100 was administered one and a half hours before operation and followed by a second injection of morphine gr. 1/6 and scopolamine gr. 1/200 half an hour before the block analgesia was given. In the cases where a general anæsthetic was used the preliminary injection consisted of morphine gr. 1/6 or 1/4 and atropine gr. 1/100 half an hour before operation. The general anæsthetics he preferred were gas and ether, or a mixture of chloroform and ether. In view of the preliminary fall of blood pressure he advised that care should be taken to avoid raising the shoulders. Since regional blocks could not be hurried he emphasized the necessity of co-operation between surgeon and anæsthetist. It was necessary that the surgeon should indicate clearly the area within which he proposed to operate, and that he should confine his manipulations to the anæsthetized area unless he had warned the anæsthetist to deepen the general anæsthesia. Great care should be taken in moving patients after this type of anæsthetic. It was possible to reduce considerably the amount of novocain used, and it was perhaps best to do this by reducing the strength of the solution. Satisfactory anæsthesia could be produced with 1/2 per cent. solutions. In addition to the disadvantages mentioned by Mr Hillman there were two others. Patients complained sometimes of backache, and Mr Apperly had also encountered cases of regurgitation of the stomach contents when that organ was manipulated by the surgeon. If possible, in these cases a stomach tube should be passed and the stomach washed out, but this was sometimes difficult owing to the light general anæsthesia used. He had never seen any sequela to this accident.

Mr GORDON TAYLOR, whose patients supplied the majority of the cases under review, fully concurred with these observations, and said that the method had enabled him to perform successfully operations which he felt sure would have been fatal if performed under general anæsthesia alone. Only one patient had developed pulmonary symptoms, from which he died, and in no other case were previously existing chest troubles aggravated by the anæsthetic used. The method was a distinct advance in the art of anæsthesia, it was one which anæsthetists should take up, since the surgeon had enough responsibility already, and it was not possible in the same case to have two anæsthetists—one for the general anæsthesia and one for the block analgesia.

Mr STANFORD CADE had employed this method in some fifty cases and always used a 1/2 per cent. solution. He emphasized the danger of novocain poisoning if even small quantities of the drug entered a vessel. Palpitation and cyanosis were the preliminary signs of poisoning, and if the drug passed into the circulation there was immediate apnœa. He showed a number of tracings from animals demonstrating the effects of injecting novocain into the circulation. In all cases the result was death even when such small amounts as 20 minims were injected. He added that this was a quick and painless method of destroying animals.

Dr HUGH PHILLIPS asked what was the average duration of block anæsthesia. Dr C. F. HADFIELD asked whether splanchnic analgesia lasted longer than abdominal block analgesia, and whether fatter patients could be dealt with according to the measurements given by Mr Hillman when inserting needles to definite depths. He also wished to know how this form of analgesia appealed to private patients. Dr LANGTON HEWER had so far tried the method in nineteen cases, he had found that the average pulse rate in these was only 91, and that shock was much diminished.

Dr J. BLOMFIELD was glad that no speaker had mentioned the addition of adrenaline to the novocain solution. He advocated abolishing the use of this dangerous drug

DR HOWARD JONES asked whether blood was ever withdrawn after inserting the needle DR H W FEATHERSTONE inquired if weakening of the diaphragm or massive collapse of the lung had ever been observed after splanchnic analgesia

MR HILLMAN and MR APPERLY replied to the questions The duration of analgesia was from one and a half to two and a half hours The abdominal block was less persistent than the splanchnic, possibly because of the better circulation of the abdominal muscles, and partly because it was more difficult to ensure adequate analgesia of the nerves of the abdominal wall owing to the indefiniteness of the landmarks The fatness of a patient did not render the method much more difficult, since the landmarks mentioned had to be found, and it was not hard to make allowances for the depth of tissues to be traversed before reaching the landmarks Since in most cases an inhalation anaesthetic was given in addition to the block analgesic, private patients had no objections to the procedures adopted On several occasions blood had been drawn into the syringe when aspirating prior to injection

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH

A CLINICAL meeting of the Medico-Chirurgical Society of Edinburgh was held on November 19th, SIR DAVID WALLACE, the President, in the chair Among the many cases shown were the following

MR QUARRY WOOD showed a patient of 21, from whom a sarcoma of the proximal end of the humerus had been successfully removed by interscapulo thoracic amputation by the posterior method introduced by the late Mr Littlewood

SIR NORMAN WALKER showed a patient with leprosy, whom he had previously exhibited to the society, to demonstrate the remarkable progress she had made under treatment by a vaccine prepared from one of the excised nodules He also demonstrated a series of cases of lupus in all stages of chronicity to illustrate the excellent results obtained by the use of artificial sunlight, far in excess of those from any other treatment he had tried The healing scar tissue was softer and more pliable than that produced by any other method, and was therefore practically painless

SIR HAROLD STILES showed two cases of resection of the ileo caecal region for tuberculosis The first patient was a woman, aged 35, who had a chronic apical lung lesion About six months ago an anastomosis was made between the transverse colon and ileum owing to there being symptoms of chronic obstruction, and six weeks ago the resection was performed The second patient was a girl, aged 20, a farm worker Five years ago resection of the ileo caecal region and proximal colon was performed for hypertrophic caecal tuberculosis, probably of bovine origin She also had had an anastomosis made for chronic obstruction three months before the resection operation She looked the picture of health, and there was no lung lesion He also showed a lad, aged 17, one month after an operation for tuberculosis of the thyroid causing much suffocation from tracheal pressure The appearance at first sight suggested a malignant condition, tracheotomy was necessary

PROFESSOR LOVELL GULLAND showed a female patient with pellagra, and described the etiology of the disease and its essential clinical features This patient developed the symptoms during a "strike" time in the village where she lived, what little food she got consisted of small quantities of bread and margarine She still had a sallow appearance, but was vastly improved in health

MR SCOT SKIRVING showed again to the society a case of marked depressed fracture of the occipital bone with effusion of cerebro spinal fluid Three further aspirations had been necessary, and a month ago half an ounce only of cerebro spinal fluid was removed There had been no general or focal symptoms of any kind, and the aspirations had caused no faintness or headache He also showed a girl, aged 3, who swallowed a hatpin about 2½ inches long The pin had perforated the duodenum, and its point was impacted in the cortex of the kidney its track was covered with plastic peritonitis The pin was removed by operation and demonstrated to the society, with an x ray photograph of it in the abdomen

DR ROBERT A FLEMING showed a man, aged 60, with neuro fibromatosis of wide distribution involving symmetrical areas of the fifth cranial nerve, nerves of the scalp, cutaneous nerves of the arms, intercostal nerves, and the cutaneous nerves of both thighs There were no lesions below the knees, and nearly all the lesions were sessile A section of one of the tumours was shown to be almost entirely fatty in nature The relationship between neuro fibromatosis, von Recklinghausen's disease, and molluscum contagiosum was discussed.

DR DOUGLAS GUTHRIE showed a man, aged 35, after total laryngectomy for epithelomata of the larynx A preliminary tracheotomy, together with the removal of a portion of the tumour, was effected under local anaesthesia, and the later removal of the larynx was performed under general anaesthesia Small drains were inserted at the extremities of the lateral flaps, the wound being sutured at the operation The patient was fed by a nasal tube kept in position for three weeks

MR GEORGE CHIENE showed a male, aged 18, suffering from elephantiasis of the left leg and scrotum The patient had never been out of Scotland In 1914 he received an injury to the knee joint, and the limb was in plaster for six months, the joint was excised later In 1921 swelling of the leg began, and spread up the limb, involving the scrotum In December, 1923, the tensor fasciae latae was exposed and three long strips of the ileo tibial tract were cut, their bases being left intact One was brought up on to the under surface of the abdominal wall, and the others embedded in the muscles of the thigh Great reduction of swelling followed

MR J N J HARTLEY showed a miner, aged 52, admitted with symptoms of concussion following a cycling accident He regained consciousness on the third day, and seemed to be making good progress till the tenth day, when twitchings followed headache and drowsiness On the next morning a severe spasm occurred, affecting the whole body The patient became unconscious, and developed complete paralysis of the left arm and leg and the left side of the face A right temporal exploration disclosed a subdural clot extending over the cortex throughout the area exposed in the temporal fossa, a little turbid fluid was withdrawn A film was made of this fluid part of the clot, and among the polymorphs were found a few minute Gram positive cocci The patient made a satisfactory recovery

DR CHALMERS WATSON showed a case of disseminated sclerosis of five years' standing The patient had twice been in hospital before, and had been discharged with slight improvement Since June, 1924, steady deterioration had set in, and before his admission to Dr Watson's wards he had been unable to stand or walk, he was later confined to bed or a chair He was treated by Dr Watson's method of combating auto intoxication, and already showed marked signs of improvement He was still very tremulous, but was able to stand alone with the help of a stick

DR W T RITCHIE showed (1) A case of acromegaly The patient, aged 28, was 6 ft 6 in in height and weighed 217¾ lb He showed the features of gigantism characteristic of over activity of the anterior lobe of the pituitary Before epiphyseal union in the long bones was complete, and acromegaly, the result of the same hypophyseal disturbance after ossification of the epiphyses He had suffered much from headaches between 11 and 16 years of age Dr Traquair at that time had detected some bitemporal hemianopia, which had not progressed (2) A case of Erb's paralysis in a man, aged 29, who had been struck between the neck and shoulder by a sandbag in the trenches in 1916 Six months later symptoms began with the finding that he could not handle his rifle properly

DR CHARLES MCNEIL showed (1) A case of pyloric stenosis in a boy, aged 5 months, illustrating the importance of establishing the diagnosis early while the child was being breast fed The diagnosis was made when the child was a month old, at the first examination, lavage twice daily was instituted and breast feeding continued Progress had been slow, but quite steady (2) A case of interlobar empyema after pneumonia in a child, aged 7 years 11 months Repeated puncture in the lower axillary region was negative, but finally pus was obtained in the third interspace in the mid axillary line Five ounces were withdrawn and a cannula inserted, which was removed two days later because only serous fluid was being discharged Radiographs illustrated the gradual disappearance of the lesion, and the final photograph showed complete resolution

MR FRANCIS E JARDINE showed a case after operation for a retroperitoneal strangulated hernia, 28 inches of gangrenous small intestine were removed, beginning about 1½ inches above the ileo caecal junction Inside the resected bowel a sarcomatous tumour was found, which was, no doubt, a factor in causing the hernia

MR PIRIE WATSON showed a man, aged 68, after operation for the removal of a very large omental cyst which had caused singularly few symptoms The tumour was too large to remove despite a large incision, and a trocar was passed into it, allowing 1½ gallons of haemorrhagic fluid to be withdrawn The pathological report by Dr James Davidson indicated that it was a malignant endothelioma with invasion of the cyst wall, and a bacteriological examination by Dr McCallum showed the presence of *B coli* It was probable that the cyst had been of long standing, and had only recently taken on malignant features

MR J J M SHAW showed a man, aged 28, who received a shrapnel wound of the thigh in 1918 He came to the out patient department complaining of pain in the lower part of

the thigh, and on x ray examination nine and a half sewing needles were found in the left thigh It appeared that he had put a new housewife into his trousers pocket shortly before being wounded and the needles had presumably been blown into the limb, becoming dispersed in the muscles

A MEETING of the Plymouth Medical Society was held on November 25th the President Mr C L LANDER, in the chair Mr C HAMILTON WHITEFORD read a paper on some unusual surgical cases The list of cases was Death in convulsions during chlorotorm anæsthesia intraperitoneal rupture of the bladder, epithelioma of the penis following incomplete circumcision exstrophy of the bladder in an adult, failure of union between the vas deferens and the testicle, epithelioma of the tongue in a woman of 25 adenoma of the umbilicus, enteric spasm of the small intestine involving a long segment of bowel strangulation of the descending colon in a right femoral hernia sarcoma of the rectum, carcinoma of the rectum occurring simultaneously in husband and wife complete tear (non obstetrical) of perineum, causing rectal incontinence pyophlebometra A discussion followed, in the course of which Mr H E VELLACOTT and Mr J W G H RIDDEL mentioned a case of two girl friends of 18 and 21 who had occupied the same bed and were both found to be suffering from carcinoma of the rectum

Reviews.

PNEUMONIA

At the time of the late Dr R MURRAY LEIPER's death in March, 1921 it was stated in our columns (1921 i 548) that he had completed a work on pneumonia and its modern treatment for the Oxford Medical Press Dr J BROWNING ALEXANDER has now revised and edited the posthumous book and brought it out under the title *Pneumonia its Pathology Diagnosis Prognosis, and Treatment*[1] From the editor's preface it appears that in the original form of the work much more importance was attached to vaccine treatment than the author would probably have thought judicious had he survived to the present day, accordingly much that was then written has been modified or omitted and considerable additions have been made in the chapters dealing with bacteriology It may be said at once that the result of Dr Browning Alexander's editing has been successful, and that there is thus provided a good general review of pneumonia and bronchopneumonia with evidence of wide reading and numerous quotations from the writings of others, including the author's three chiefs ' at the Brompton Hospital for Consumption and Diseases of the Chest—Dr J Mitchell *Bruce, Sir James Fowler and* Dr *Percy Kidd—to whom* it is piously dedicated The ground covered is large, and it is convenient to have the subjects—which are included of course, in textbooks and treated individually in scattered papers, but seldom made the object of a monograph—between the covers of a well printed volume

In addition to ordinary pneumonia, there are chapters on influenzal pneumonia, pneumonia in children and surgical (post-operative) pneumonia The account of the lung complications of influenza appears to be based largely on the discussion that took place at the Royal Society of Medicine in November, 1918 and it might have been well to have referred, especially in the sections on the vexed question of the bacteriology and on the morbid anatomy to Dr Crookshank's *Collected Essays on Influenza* (1922) and to the reports from the American camps, particularly to those by W G MacCallum and E L Opie It is, of course, difficult to include every opinion, but it may be noted that the late G A Gibson's attractive dictum (1908) that the arterial blood pressure expressed in millimetres of mercury should not fall in pneumonia below the pulse rate expressed in beats per minute has, even with the admitted exceptions, hardly met with universal confirmation for Newburgh and Minot (1914) in America, and Geoffrey Evans (1920) in this country, have found that the blood pressure was higher in the fatal than in the surviving cases of pneumonia The account of the treatment of pneumonia is commendably full, and contains a good description of the use of digitalis, the observations justifying its employment, made at the Rockefeller Hospital, New York, being quoted, strychnine is also recommended, in spite of some adverse opinions, as of great value in a failing heart and falling blood pressure The uses and common mistakes made in the technique of oxygen inhalation are discussed in a thoroughly practical manner

In conclusion it may be said that this work will serve as an extremely useful source of reference to medical practitioners

THE PRINCIPLES OF BIOCHEMISTRY

OPIE, when questioned said he mixed his paints with brains, the author of *Principles of Biochemistry* may be said to have mixed his with philosophical common sense The result is very satisfactory, for we have a series of essays on the various aspects of vitality rather than a catalogue of unrelated statements about chemical substances Professor BRAILSFORD ROBERTSON uses his chemical knowledge to interpret function rather than isolate from each other in two watertight compartments all he knows about chemistry and physiology respectively

The author's treatment of the part played by inorganic substances in the body may be cited in illustration of this *Instead of an enumeration of the inorganic salts in the* tissues, blood, and urine, we have in Chapter II an illuminating account of the physiological importance of water, sodium chloride, calcium and iron And the treatment is not elementary, it is taken for granted even so early in the book that the reader is familiar with nucleo-proteins, "haematogen," scurvy anæmia chlorophyll, and selective absorption in the thyroid Nor does this exhaust the subject, for under the heading Effects of the disturbance of the inorganic environment" the author later on returns to his thesis of the enormous importance of inorganic materials Professor Robertson quite candidly announces that in order to comprehend the biochemistry of to-day the student must have had some training in the use of the differential and of the integral calculus and have read something on the method of least squares, the theory and practice of interpolation, the theory of statistics and the conception of probability The sections into which new matter has been incorporated since the first edition are those on—neutrality of the blood metabolism in diabetes, and the biochemistry of growth Certain subjects are now treated for the first time these include the relation of growth to diet, the racemized proteins, the nucleic acids, and the inclusion of the environment in evolution

The chapter on "Chemical correlations" instead of being a summary of other people's work on the internal secretions is a masterly survey of the whole field of endocrinology but we are surprised to find only the barest reference to insulin, a substance fully proved to be of the highest importance for carbohydrate metabolism and one discovered, to boot, in Professor Robertson's old University of Toronto

The second part of the book is wholly occupied with a valuable discussion particularly illuminating for all students of physiology At the same time no artificial line is drawn between the facts of physiology and pathology, so that we find such subjects as the production of antiserums and the theory of antigens ably treated Where so much else is to be found in this large volume, we are disappointed to note that certain topics are virtually ignored these include filtration through compressed clay filters the reducing powers of the tissues, and latent life Rectal feeding is not fully discussed Even so original a writer as Dr Robertson does not attempt to deal with the problem of the reality of nerve energy surely in the last analysis a chemical one This is the more curious as he does treat of sleep and memory It seems to us that phase" is a better term than cycle" to describe the waves or oscillations on the curve of the growth of the individual, and we also think that of the two phrases inertia" or lag" (on page 555) the former, when referring to functional or physiological inertia, is to be preferred

[2] *Principles of Biochemistry for Students of Medicine Agriculture and Related Sciences* By T Brailsford Robertson Ph D D Sc Second edition London Bailliere Tindall and Cox 1924 (Roy 8vo pp xii + 796 57 figures Ls net)

The text is not interrupted by footnotes, but all the titles of papers referred to are classified in a convenient fashion at the end of each chapter The illustrations mainly consist of curves, but there are one or two excellent photographs of cases of disordered internal secretion

There are two indexes—one of subjects and the other of authors

The printing is excellent, and the use of heavy type to indicate topics under discussion has much to commend it, but the paper is so heavy that the book cannot be held in the hand without fatigue

MENTAL NURSING

IN addition to the regular course of instruction given to the staff of The Retreat, York, it has been the custom for some years to ask well known psychiatrists to give addresses at the hospital on topics connected with mental nursing These lectures, fifteen in number, have now been arranged and edited by DR BEDFORD PIERCE, and published in a volume entitled *Addresses to Mental Nurses*[3] Perhaps the most noteworthy feature of these addresses is the atmosphere of idealism with which they are permeated Nearly all the speakers emphasize the fact that the care of the insane, which is certainly one of the most exacting and difficult tasks which anyone can undertake, requires not only technical knowledge but a spirit of service as well Several of the addresses, indeed, are largely concerned with a study of the character traits which are an essential part of the equipment of those who aspire to be successful mental nurses

We regard this book as an important addition to the literature of mental nursing It is a work which every mental nurse would do well to possess as a supplement to the ordinary textbook, for not only does it furnish a great deal of practical information, but it encourages an attitude of optimism and hopefulness in a sphere of activity which is liable to provoke despondency Five of the contributors to this volume—namely, Dr David Yellowlees, Sir Thomas Clouston, Dr Charles Mercier, Sir George Savage, and Dr James Middlemass—have died in the last few years, and it is satisfactory to know that their teaching will still continue to inspire the work of the present and coming generations of mental nurses

INDUSTRIAL FATIGUE

MUCH interest has been taken in recent years in the study of fatigue, especially in relation to problems of industrial efficiency Numerous tests of fatigue have been proposed and practised They are of two categories One set of tests is concerned with the study of fatigue in the individual, and includes both physiological and psychological tests The other is concerned with fatigue in the mass, and is based on deductions made from industrial phenomena which may be looked on as representing the total individual fatigue reactions Dr DHERS, who has written a small book entitled *Les Tests de Fatigue*,[4] is sceptical of the practical value of fatigue tests He does not consider that the sensation of fatigue is in any way a reliable index of the presence of real fatigue

In the first part of the book we have a detailed consideration of the several tests in use Dr Dhers is a keen critic and indicates many fallacies in them In the second part, after enumerating the many factors productive of fatigue in industrial work, he goes on to consider its supposed sequelæ (diminished output, etc) Dr Dhers contends that the value of such methods of inquiry is limited, and deprecates hasty conclusions He considers that the problem of fatigue tests is essentially limited by our ignorance of the underlying biological phenomena

Dr M H PIÉRON, Professor of Experimental Psychology in the University of Paris, in an excellent preface, deservedly congratulates Dr Dhers on having set out clearly the real problems involved Thus only can real progress be made

A FAITH-HEALING NOVEL

NOT a few eminent authors have had a medical training when young But it is rare to find a busy medical man who is also a novelist Professor F E WYNNE, M O H Sheffield, is one of those who combine the two occupations, and following his earlier novel, the *Mediterranean Mystery*, he has now produced *Digby's Miracle*[5] The subject of the book is appropriate to the present time when newspaper columns are filled with the marvels of faith healing, and it is perhaps useful that the cold douche of comedy should be applied, by one who has been trained in medicine, to the fiery enthusiasm of faith healers Margaret Hesford, who had been stricken with paralysis at the age of 12 years, is 20 when the novel begins During the eight years that she had lain in bed she had become the local saint of the uninteresting village of Kinderwell Into this village there comes the young Dr Digby, compelled by lack of means to abandon his ambition to do research work in a London hospital He discovers that the paralysis is simply hysterical, but is faced with difficulty in adopting treatment —difficulty due partly to the inconvenience of destroying in a moment the saint's reputation in the small village, but arising even more out of pity for the girl's mother, one of the few unselfish characters in the book, who has slaved for eight years in her daughter's interest In this dilemma the doctor hits upon the idea of making a miracle of the cure, the patient is carried in her spinal carriage to a disused well, labelled for the occasion St Kilda's Well, with a suggestion that from it the village derived its name, and with a glass of water from this well an immediate cure is effected Unfortunately, Dr Digby's ingenuity leads him into a series of troubles the prickings of conscience, love-making, and later hate on the part of his patient, and, most embarrassing, booming of the miracle by the press throughout the country Kinderwell is thronged by the sick, further miracles are reported, the fame of the cures spreads publicans, Jews, reporters, and a disreputable ex gaol bird of a revivalist who starts the singing of hymns at the well, all take a hand in the organization of the healing business Dr Digby ends by falling in love with a charming female reporter, whose disillusionment is great when she learns all about the doctor's deception But the *deus ex machina* in the shape of Lord Altadore, the landowner of Kinderwell, sets matters right, and finally disposes of the miracle working well by sending for geological experts, who successfully drain it away

The story is amusingly told, but perhaps is almost overladen with cynicism The character of the paralysed girl puts a strain upon one's credulity Professor Wynne appears to suggest that she knowingly practised fraud from the age of 12 Her proceedings when cured are by no means saint-like But it is difficult to believe that after lying in bed for eight years she should have been able, at the age of 20, so to impress a Jew film producer with her powers as an actress that he forthwith engaged her for a cinema production Possibly Professor Wynne wished to eliminate an undesirable aspirant for Dr Digby's love in favour of the later introduction, the reporter Lucretia Bourne The author's style and views may perhaps be illustrated by such remarks as these "Nationalization would divert the profits from one set of pockets to another" "Talking politics is generally a swopping of catchwords" "As far as I can make out, 'democracy' is a system of counting heads and ignoring their contents"

NOTES ON BOOKS

AT the age of 87 Dr W W KEEN of Philadelphia has produced his "Religio Medici" under the title *Everlasting Life*[6] As a boy Dr Keen was brought up a member of the first Baptist Church His imagination was affected by prophecies of the "second Advent," which was to occur in 1843 and usher in the millennium The excitement caused by these prophecies was intensified by various unusual appearances in the heavens—mock suns and the great comet of 1843 But as he grew older his idea of a revengeful God became modified, and building on a text which he describes as the

[5] *Digby's Miracle* By Fred E Wynne London Herbert Jenkins, Ltd 1924 (Cr 8vo pp 310 7s 6d net)

[6] *Everlasting Life A Creed and a Speculation* By W W Keen M D LL D London J B Lippincott Company 1924 (Cr 8vo pp 85 4s 6d net)

glorious Christian Magna Charta, he gives his views of the essentials of Christian belief. Without disputing the faith of those who think otherwise, Dr. Keen finds no demand for belief in a miraculous virgin birth. To him Nature is only another name for God. He regards the Incarnation and the Atonement as essential to faith, which to him is as much a normal function of the human mind as is logic. Being convinced of immortality the author concludes with a speculation on "How shall we spend our time in heaven?" The little book is the work of an earnest and simple minded Christian well versed in scientific knowledge who finds no difficulty in reconciling the discoveries of science with the essential beliefs of the Christian religion.

We welcome the appearance of a cheaper unabridged edition of the late Dr. R. W. S. Bishop's book entitled *My Moorland Patients*, the first edition of which we reviewed some years ago (JOURNAL, June 3rd 1922, p. 878). By its happy combination of lively humour, keen sympathy, and sombre realism the work deserves to become a classic of its kind.

We have received a copy of a short memoir of the late Dr. Thomas Bodley Scott, who was mayor of Bournemouth at the time of his death. An obituary notice appeared in our issue on February 16th last. The little work, which has been edited by W. V. I. and "G. R. D.," contains chapters on T. B. Scott, the Doctor, by Dr. C. Hyla Greves; His Religion by the Rev. E. Moor, and His Writings, by G. R. Dennis, as well as a short account of his public work.

The first issue of the *Revue Franco-Russe de médecine et de biologie*[9] a new monthly journal edited by Drs. L. HACHLOVITCH, J. LEVITCH, Z. PELICHEFF, and A. ROUDAKOFF, contains original articles by Professor Diakonoff on a new anthropometric method, by Professor Semaschko on hygiene in Soviet Russia and by Dr. Dobreitzer on malaria in Russia, an account of the third Pan-Russian Congress for Combating Tuberculosis, and abstracts from Russian journals, and medical news.

The sixty-fourth issue of the *British Journal Photographic Almanac*[10] for 1925 is again edited by Mr. GEORGE E. BROWN who contributes to it a valuable article entitled "The plain facts of lenses." Another article by Mr. T. L. J. Bentley contains a useful discussion of the small camera with many practical hints. The present issue contains several new features and is larger than its predecessors, more pages being added to the text and reviews of many improvements in apparatus and materials being included. A series of short articles dealing with the properties of chemical substances used in photography is particularly helpful. The table of exposures has been extended to apply to countries in every latitude, and the book can be confidently recommended; the price is not increased.

A volume containing the *Transactions* of the Tenth Annual Conference of the National Association for the Prevention of Tuberculosis[11] has been published. This conference was held on July 3rd and 4th 1924, and was reported in our columns of July 12th (p. 61). It was chiefly occupied with the consideration of training colonies and their place in the tuberculosis scheme.

My Moorland Patients. By a Yorkshire Doctor (the late Dr. R. W. S. Bishop). Cheaper Unabridged edition, edited by J. C. Lewin. London: John Murray. 1924. (D. my 8vo, pp. viii+212, 4 plates. 7s. 6d. net.)

[9] *Thomas Bodley Scott, Mayor of Bournemouth*. Bournemouth: Ernest Cooper. 1924. (Cr. 8vo, pp. 93, portrait. 1s. net.)

[9] *Revue Franco-Russe de médecine et de biologie*. Paris: Société d'éditions scientifiques. "France-Russie." (Subscription: France, fr. 30; Union Postale, fr. 40; single copy, fr. 4.)

[10] *The British Journal Photographic Almanac*. Edited by George E. Brown, F.I.C., Hon. F.R.P.S. Sixty-fourth issue. London: Henry Greenwood and Co., Ltd. 1925. (Sup. roy. 16mo, pp. 814, illustrated. Paper, 2s.; cloth, 3s. net.)

THE LEAGUE OF NATIONS HEALTH COMMITTEE

THE League of Nations Health Committee held its third session in Geneva from September 29th to October 4th. Sir G. S. Buchanan, C.B., M.D., represented Great Britain. The committee adopted a report prepared by the subcommittee it had appointed at the request of the Advisory Committee on Traffic in Opium and of the Preparatory Commission for the International Opium Conferences. This report gives information in support of the estimated figure of 450 milligrams of raw opium and 7 milligrams of cocaine per inhabitant per year as the maximum for legitimate requirements of European countries possessing a well developed medical service. The Health Committee further decided to request the opinion of medical practitioners in different countries as to whether the therapeutic value of heroin is sufficient to outweigh the social dangers which its abuse entails. It recommended that propaganda against the abuse of cocaine and morphine should be confined to doctors and medical students, as it might otherwise do more harm than good by arousing unhealthy curiosity, and that preparations containing less than 0.2 per cent. of morphine or 0.1 per cent. of cocaine or heroin should also be included in the provisions of the Hague Opium Convention. The Health Committee approved the report submitted by the joint committee formed by members of the International Labour Office and the Health Committee to study the question of the disinfection against anthrax of leather and hides. The report recommends that members of the joint committee should study in their own countries the various methods of disinfection with a view to comparing their value, and that national committees should be formed in Belgium, France, Germany, Great Britain, and perhaps Switzerland and the United States for conducting further investigations. The liaison between these organizations and the joint committee should be assured by the International Labour Office.

The Health Committee, in pursuance of the proposal submitted by the Dutch Government relating to the simplification of quarantine and clearance formalities, decided to frame a model convention that might serve as a basis for the conclusion of special conventions whose purpose it would be to eliminate the unnecessary repetition of sanitary measures on ships. The Dutch and Belgian Government opened forthwith negotiations for the conclusion of a convention of this kind.

The committee adopted the report of its subcommittee on health instruction, suggesting a course of study for 1925, to comprise notably the collection of information relating to instruction in health matters for medical students and medical experts in European and, perhaps also in Canadian and American universities.

The Malaria Commission submitted a provisional report on its investigation in Bulgaria, Greece, the Kingdom of the Serbs, Croats, and Slovenes, Rumania, Russia, and Italy. The final report, which is being prepared to the end of this year, will contain exhaustive information as to the incidence of malaria and the methods used to combat it in all the countries visited. At the same time the Health Committee considered the first reports of its small committee of experts on the problem of quinine, and decided to recommend that attempts should be made in Algeria, Spain, Italy, and Rumania to try the effect of the various cinchona alkaloid. The experiments will be carried out under the auspices of the League Malaria Commission, and with the aid of material furnished by it, so as to ensure uniformity of conditions. Further, the Malaria Commission will continue its study of the incidence of malaria in Europe by establishing contact with experts and corresponding members, and by investigations in Sicily, Tunis, Algeria, Morocco, Spain, and Portugal during 1925.

The committee, after considering the report submitted by its subcommittee on sleeping sickness and tuberculosis in equatorial Africa, asked the Council to recommend to the Governments concerned that they should encourage conferences between governors and health officials in the affected territories as well as organize a regular interchange of information on all matters concerning the spread and incidence of sleeping sickness. The committee drew attention to the desirability of maintaining a medical service proportionate to the population and areas to be dealt with, and recommended a programme of technical research with regard to certain questions connected with the origin and spread of sleeping sickness.

The Health Committee approved the preparatory work for the opening of the Epidemiological Intelligence Office at Singapore, and notably the organization of a conference of health officials to be held in Singapore at the beginning of next year, at which Dr. Norman White will attend on behalf of the League Health Organization.

The committee instructed the Health Section of the Secretariat to prepare a preliminary report to serve as a basis for the adoption of a programme of investigation with regard to an antituberculosis campaign, as requested by the Fifth Assembly, and asked its presidents and vice-presidents to keep in touch with the preparatory work. A suggestion of the Japanese member that the Health Committee should investigate the standardization of tuberculin and study the methods for the preventive and early treatment of tuberculosis was adopted, the question of tuberculin being referred to the permanent subcommittee on the standardization of sera and serological tests.

The Health Committee, in approving the system of interchange organized for the year 1925, paid special attention to the arrangements for a South American interchange, in which ten health officials from South American countries appointed by their respective health administrations should study the working of the American, Canadian, British, and two or three Continental health services under the auspices of the League Health Organization.

consideration of the medical profession The high standard of the education at the College was manifest during the past year, when a "record" number of successes was obtained in university and other examinations Epsom College is entitled to a greater measure of support than it has yet received from the medical profession generally, out of the 350 boys in the school, 76 per cent are engaged in preliminary medical studies Details of the Royal Medical Foundation and of the Epsom College war memorial will be found in our advertisement pages this week

THE LEAGUE OF NATIONS EPIDEMIOLOGICAL INTELLIGENCE

THE Health Organization of the League of Nations has issued its statistics of notifiable diseases for 1923 [1] The statistics relate to 27 European countries, 15 African, 14 American, 12 Asiatic, and Australasia Certain reservations are pointed out in the introduction Wherever practicable the tables have been submitted to the responsible offices for their approval, but corrections have not been obtained from the more remote countries, also, efficiency of notification varies in different countries, and for this reason crude figures have been used more frequently than rates, as otherwise the reader might have been tempted to indulge in unjustifiable comparisons Geographic distribution and seasonal variations have been shown as fully as possible It is not professed that all diseases which could usefully be dealt with are yet included in the volume for 1923, but effort is being made to collect available data regarding venereal disease and certain other important causes of morbidity and death If the data so obtained are found sufficient, a supplementary volume will be issued Such a report as this cannot easily be made the subject of condensation or synopsis The statistical material is a mine from which epidemiologists may dig masses of detailed information regarding the ebb and flow of infections throughout the world, and as years go on (this being the eighth of the series) the data will become more and more valuable In the text introductory to the tables, however, the authors give a very brief indication of the position with regard to the various diseases The plague-infected area remains unchanged, India having had, as usual, the vast majority of the cases Although no very great extension has taken place, yet plague was more prevalent than in immediately preceding years Cholera, on the other hand, shows a general and marked decrease, and the death rate in India was the lowest on record Of yellow fever the outstanding feature was the entire absence of any reported case in Mexico, Central America, Ecuador, or Peru Typhus incidence in Europe was generally (with exceptions) lower than in any year since the war, and a return to pre-war prevalence is evident, Russia shows a very marked decline For small-pox the situation was favourable in Europe, notwithstanding local epidemics of mild type in England and Switzerland In Russia there has been constant diminution since 1920, though even yet that country furnishes nearly five-sixths of all the European cases The statistics of dysentery include a group of intestinal diseases of varied etiology, but amœbic dysentery is certainly uncommon in Europe Notwithstanding some increase in Germany in 1923, the general trend is definitely downward in Central and Western Europe, and in Russia since 1922 Enteric fever (including paratyphoid) has been rather more prevalent in Western Europe and less prevalent in Central and Eastern Europe Malaria was formidably prevalent in Russia, where there were over five and a half million cases, or more than double the previous year, whilst, on the contrary, there was a great reduction in Poland Dengue fever rose to unprecedented prevalence in the southern parts of the United States in the autumn of 1922 Texas had between 500,000 and 600,000 cases, the maximum being in October, the disease then declining rapidly until it became rare in February, 1923 Influenza's morbidity statistics rarely represent the true incidence, because notification is not compulsory except in a very few countries Mortality figures are more useful, and these indicate that the disease was much less severe in Europe in 1923 than in the previous winter Encephalitis lethargica was more prevalent than in 1922, but less so than in 1921 The statistics of cerebro spinal meningitis show no definite general tendency Scarlet fever prevailed throughout Europe in 1920 and 1921, and declined in 1922 and 1923, though in the latter year it increased in Bulgaria and some other countries in Eastern and Southern Europe Diphtheria shows a general decline in the last three or four years in various parts of the world—in Northern, Western, and Central Europe, North America, Japan, and Australia Measles had a low incidence in many countries, but there were severe epidemics in the United States, Egypt, and Denmark Whooping-cough is notifiable in few countries, its incidence was variable in 1923 Data for leprosy are defective In 100,000 persons examined for trypanosomiasis in the Cameroons under the French mandate there were 30,000 cases Statistics of trachoma are quite insufficient, but in countries like Egypt and Palestine 70 to 95 per cent of the population are affected Of anthrax there were in Russia 3,904 cases in 1922, and 7,801 in 1923 Under rabies it is stated that Germany had 71 cases, Czecho-Slovakia 22 (all fatal), and Latvia 21 Poland reported 2,572 cases of animal bites, of which 36 were fatal

NEAR SIGHT AND CIVILIZATION

SIR ARTHUR KEITH, lecturing at King's College on December 11th to the British Optical Association, dealt with the causes of myopia He argued that a myopic ancient hunter could not have survived, and deduced from this that in prehistoric times cases of pronounced myopia must have been unknown or very rare Modern civilization had placed men's bodies under conditions altogether new to them Hence thoughtful men were seeking to understand how our bodies reacted under the increasing artificiality of city life To the question, "What is happening to our eyes which are now overtaxed by near work?" the answer returned by ophthalmic surgeons was to the effect that civilization is threatening our eyesight They agreed that all children were born with eyes fashioned for "distant" sight—just like the young of wild animals When, however, a thousand British children were traced from infancy to adult years, it was found by the end of the fourth year that some ten or more of them had lost the power of seeing distant objects clearly, every succeeding year others suffered the same loss, so that by the age of 20 about 150 of the 1,000 had become myopic In inquiries into the nature of the disorders which overtake the bodies of men living under the conditions of modern civilization—disorders such as contractions of the palate and deformities of the jaws—he found that a study of the normal processes of growth threw most light on the manner of their production He found no data to suggest that an eye which had remained normal until the twentieth year could thereafter undergo the changes which produced myopia It might be concluded, therefore, that the causes which produced myopia were operative only in the growing eye, and that myopia should be ranked among the disorders of growth Some said it was the strain which accompanied the convergence and accommodation due to using the eye for close work This alone could not be the cause of myopia, for thousands of people strained their sight to the utmost with no ill effect on their power of vision Some said it was muscular exercise, but this alone, whether mild or severe, could not be the cause of elongation of the eyeball, for then

all athletes and gymnasts would assuredly become myopic The conclusion Sir Arthur Keith drew was that if the eye were held by it would withstand unchanged all strains— short or small, continuous or interrupted—to which it might be subjected His argument led him to suspect that the essential cause of myopia must be sought for in the behaviour of the fibroblasts, which were not only the bricklayers but also the architects of the eye It the sclerotic fibroblasts lind the structures of the eye with sound material and laid it rightly then all was well, what ever might be the use to which the eyes were put But if the material was unsound and laid wrongly, then it was possible that forces which left the normal eye unaffected might damage the abnormal eye It was on such grounds that ophthalmic surgeons instructed patients with high degrees of myopia to avoid excessive

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The London School of Hygiene and Tropical Medicine has just made two interesting appointments It has nominated Dr H H Scott at present assistant director in the department of helminthology in the tropical division of the school to be Milner Research Fellow in comparative pathology This appointment has been rendered possible by the co-operation of the Council of the Zoological Society The fruitful field of research work in the Zoological Gardens for which Dr Scott is well qualified he is not only in experienced pathologist who has done much original work in various fields but is also well versed in helminthology and protozoology He is M D M R C P London and holds the D P H and D T M of Cambridge The other appointment is of Dr Edward Hindle, M A Ph D until recently professor of biology (including parasitology) in the Cairo school of medicine to undertake research work in spirochætosis Investigations in this field are much needed and Professor Hindle's record both as a research worker and writer is such as to suggest that he has exceptional qualifications for the work The school has also determined to send out research workers to investigate diseases common to Rhodesia and tropical and subtropical Africa This decision has been come to in response to a request from Sir Frances Newton High Commissioner for South in Rhodesia made in accordance with a scheme originally suggested by Dr Andrew Fleming assistant director for Southern Rhodesia Dr Fleming has recently been in this country to discuss details with the authorities of the London school and the Government of Southern Rhodesia has undertaken to make a contribution to the school for the purposes of this research and also to provide laboratory accommodation and equipment Both in recognition of the immense importance of research into the causes of those tropical diseases which now bar the way to the full development of the highlands of central and equatorial Africa the Government of Southern Rhodesia has set a very good example

THE MEDICO LEGAL SOCIETY

The annual dinner of the Medico-Legal Society was held under the presidency of Lord Justice Atkin on December 12th The customary toast Law and Medicine was in the hands of Sir William Collins who pointed out the various parallels between the two professions In Germany the common territory between medicine and law was spoken of as state medicine in France as medecine legale, and in this country as medical jurisprudence which was the title of the first work on the subject in English, by Samuel Farr, published in 1788 The subject was of wide range, from the exactitude of the chemist and microscopist on the one hand to the maze of psychiatrists on the other criminal responsibility or the insane on the one hand, but much hope of rapid materialization, to the proposal that an institute of forensic medicine should be founded in London, where by the faculty would be concentrated in one centre instead of being divided among a dozen medical schools Sir Humphry Rolleston, President of the Royal College of Physicians responded to the toast on behalf of the medical side of what he called the holy alliance Of the two divisions or the medical profession he could not help feeling that medicine or physic was more closely allied to law than was surgery A very good definition of surgeons had been put forward by one of them— that the surgeon was a physician who could use his hands, to which however, it might be retorted that the physician was a surgeon who could use his brain But physicians and lawyers had this much in common, that both of them depended for their professional success upon their offered to the medical profession by the Medico-Legal Society linking the two professions, expansion or outlook and in opportunity to become wise in the many legal bearings of medicine Mr T P Hughes, K C, President of the General Council of the Bar, responded on behalf of the legal profession Mr Justice Eve in proposing the toast of prosperity to the Medico-Legal Society said that no one who took even a cursory glance at the subjects with which the society had been dealing could fail to appreciate its value to both branches of its membership He hoped that from its further discussions some clearer light would emerge on the criminal responsibility of the mental degenerate (for no one was satisfied with the present position) and on questions connected with workmen's compensation such as industrial diseases malingering and partial as against total disablement Lord Justice Atkin in reply, said that there were very few persons now in either the legal or the medical profession, who had not some idea of the operations and value of the society The society, which had now passed its majority and was increasing in its membership acted as a liaison organization between the two professions both of which were sincerely seeking after truth although each approached the subject from different angles and were it not for such a society would rarely be able to reconcile their points of view Two subjects—namely criminal responsibility and professional privilege— till awaited the latter already done valuable work He could be said A further advantage of the society was that each side learned to know some of the idiosyncrasies of the other no doubt to such an extent that lawyers could practise more effectively as physicians practise law but a lawyer at least found great benefit to his practise from some knowledge of medical jurisprudence The course of elementary lectures on medical jurisprudence given recently by Sir Bernard Spilsbury under the auspices of the Council of Legal Education had also been worth a guinea attendance at the lectures must have been worth that to many barristers engaged in criminal work to any considerable other £500 a year It had always been to him a marvel that so many laymen whose business and private life was subject at all points to legal interference or direction remained in ignorance of law but he had to say also that a very large number of doctors although they might be required to give evidence at any moment went through their professional lives without any appreciation of the rules of evidence

CHARCOT CENTENARY

Paris is preparing to celebrate the centenary of Jean-Martin Charcot, who was born in 1825 and died in 1893 In 1862 he became physician to the Salpetrière Hospital, where he gradually built up the world-famous neurological clinic The centenary organizing committee under the patronage of the President of the French Republic and the leadership of statesmen and scientists of France, includes a[illegible]ns Pierre Marie, Albert Pierre,

and Paul Richer, who were pupils and colleagues of Charcot The president of the committee is Professor Babinski Early in June commemoration ceremonies will be held in Paris by the Academy of Medicine, the Faculty of Medicine, and the Paris Society of Neurology This society will hold at the same time its sixth international neurological reunion, celebrating the twenty-fifth anniversary of its foundation and the work of Charcot Foreign Governments, universities, and scientific societies will be represented by delegates, and a large number of neurologists from many countries have signified their intention of joining in the celebrations A detailed programme is being prepared, and may be obtained later from Dr A Souques, the general secretary of the organizing committee, 17, Rue de l'Universite, Paris, VIIe

A DEGREE IN ORTHOPAEDICS

Some years ago the University of Liverpool established the degree of Master of Orthopaedic Surgery A candidate for the degree is examined in the principles and practice of orthopaedic surgery, and before presenting himself must have attended courses of instruction approved by the university, including a course of at least fifteen months in clinical orthopaedic surgery Masters of Surgery of an approved university, and Fellows of the Royal College of Surgeons of England, Edinburgh, or Ireland, or of the American College of Surgeons, may be exempted from courses in anatomy and physiology and in pathology and bacteriology, but must attend courses in radiology and physiotherapy and in general surgery, as well as that in orthopaedic surgery The degree has just been conferred for the first time The recipient is Mr E B M Vance, M S Sydney (N S W), who has resided in this country to go through the course of clinical orthopaedic surgery, which, as we have said, occupies fifteen months So far as we can ascertain Mr Vance is the first recipient of an orthopaedic degree, certainly in this country, and probably in the world

TEETH OF MAORI AND BRITISH IN NEW ZEALAND

A comparative study of the jaws and occlusions of a certain number of Maori and of British born in New Zealand was brought before the Society for the Study of Orthodontics at its December meeting by Miss V H George In the course of her work for the Research Committee of the Dental Board at the Royal College of Surgeons, Miss George was asked to examine a number of plaster casts sent from New Zealand, these casts were obtained from twenty Maori and twenty men of British colonial stock on their return to the Dominion after the war and before demobilization In all the Maori casts the palates were well formed, usually spreading in a wide arch containing the full number of teeth, and normal occlusion was apparently the rule In the British casts, on the other hand, the arches were comparatively small and crowded, while the occlusion, which was usually subnormal, also afforded a notable contrast to the Maori series She gave some average measurements based on these casts, showing the greatest width between the buccal surfaces of the canine teeth, the second premolars, and the molars, also the length of the palate obtained by taking a line drawn from the mid-point between the central incisors to the mid-point of a line connecting the last molars They fully supported the statements quoted above Miss George added that it appeared from descriptions by those who had studied the Maori at close quarters that their other physical characteristics were as markedly different from those of New Zealanders of the British race as were their jaws and occlusions The New Zealand colonist had much the same physique as the average Englishman—medium height and build, with a rather long, narrow face, orthognathous profile, and brachycephalic skull The Maori, according to Mr Pember Reeves, a former Agent-General for New Zealand, are tall and bulky, long bodied, short-legged, with a fairly large pyramidal skull, showing well developed perceptive faculties and features varying from classic to negroid, and a wide though not usually a flat nose Some discussion followed on the diet of the Maori

---

Sir David Prain, C M G, C I E, F R S, M B, Treasurer of the Royal Society, and late director of the Royal Botanic Gardens, Kew, has been elected a Trustee of the British Museum

---

The first social evening of the Royal Society of Medicine in 1925 will be held on Monday, January 19th, when Dr Arnold Chaplin will give an address on some great personalities in history, good and bad, male and female The address will be illustrated by portraits During the evening Dr T M Legge, C B E, will exhibit some fifteenth century stained glass

Medical Notes in Parliament.

[From our Parliamentary Correspondent]

The House of Commons completed the debate on the Address and advanced a number of bills before adjourning over Christmas As Tuesday was occupied by a discussion on housing policy, which was initiated by the Labour party, no opportunity occurred for a general statement of the Government's policy on public health and medical administration, raised by Dr Fremantle The House is due to reassemble on February 10th

During the debate on the Address (December 10th) Major Cohen who was severely wounded during the war and spoke seated, said that medical practitioners in Swansea had been surprised at the number of men who came before them suffering either from wounds or disease directly traceable to the war but yet were not in receipt of pensions An independent medical committee formed there concluded that there were certain disabilities with regard to which it was impossible for a medical man to say definitely that they would not alter They specified organic diseases of the heart chronic pulmonary diseases, rheumatism, gunshot wounds, and diseases of the joints Major Cohen contended that it was not fair to fix a pension in such cases, and expressed the opinion that Circular 30 of May, 1924, was not satisfactory All final decisions should be made by an independent tribunal He pressed for a complete revision of final awards which were under 20 per cent disability

Ex Service Mental Cases—Major Tryon, the Minister of Pensions in reply to Sir Herbert Nield on December 11th deprecated the description of public asylums as pauper lunatic asylums, it was gravely misleading and needlessly offensive Ex service men who were as certified patients under the general law of the land, in public asylums were there as private patients The cost of their treatment averaged 25s a week in addition to the allowances paid both to the men themselves and to their families In 1923 the Government opened two special institutions for cases where they were medically advised that a chance of recovery or improvement was offered by occupational treatment and instruction In these institutions 415 cases were now accommodated All ex service cases in public asylums were under periodical inspection by medical officers of the Ministry and of the Board of Control, and every case seeming suitable for treatment in some other class of institution was removed from the asylum Relatives of some of the ex service men preferred that the men should be in the county asylums

Private Mental Patients—The Minister of Health, in reply to Mr Griffiths on December 15th, said it was the practice of the Board of Control to make inquiry regarding every individual private patient admitted to an institution without having been seen by a judicial authority Mr Griffiths said that the Board of Control had reported that during 1922 at least thirty one patients were deprived of the right of appeal to a magistrate "through misdemeanour on the part of medical superintendents" Mr Chamberlain replied that no instance had come to the notice of the Board during the year 1923 of failure to comply with the requirements of Section 8 of the Lunacy Act, 1890 Mr Chamberlain further informed Mr Griffiths that it was the practice of the Board of Control to return all reception documents which did not comply fully with the requirements of Section 31 of the Lunacy Act 1890 This was done in order that the necessary information might be inserted

Indian Medical Services—Answering Dr Fremantle and Mr Wardlaw Milne, on December 15th the Under Secretary for India, Earl Winterton, said that the Government had not reached a decision on the recommendations of the Lee Commission on the organization of the medical services in India It was hoped to introduce a bill early in the present session (1924 25) dealing with the recommendations of the Lee Commission In reply to Sir Philip Richardson, the Under Secretary for India said a report had been requested from India on the application of the recommendations made in 1918 by the British Station Hospital Committee, under the chairmanship of Major General Sir George Makins This report had not yet been received.

Scotland.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY

At a meeting of the Aberdeen Medico Chirurgical Society on December 4th, with the President, Dr Peter Howie, in the chair, Mr William Anderson gave an address on his experiences and impressions during a recent visit to America, describing particularly the surgical work of the large clinics and the teaching hospitals He found the general principles of hospital administration much the same as those in this country but there was usually a much larger surgical staff in proportion to the number of beds and also a larger staff of nurses male attendants women clerks, stenographers, and photographers Out-patient departments were run mainly on the same lines but there was a much closer relationship between them and the wards A useful adjunct was the diagnostic clinic with beds for the admission of cases of undetermined diagnosis able to look after themselves where investigation for diagnosis could be carried out before their admission to the wards pressure on ward beds was thus to some extent relieved Mr Anderson then referred to the control of surgical ward work exercised by the American College of Surgeons Hospitals were graded by the College according to their efficiency, and committee visits were paid annually to inspect all facilities One very important feature of hospital work was the staff meetings these were held at least once a month and were always extremely private so that free discussion took place on such subjects as the deaths in the hospital the occurrence of epidemics in clean cases and of post-operative pulmonary complications the teaching of students, and subjects for special study Record keeping the follow up system and the social service were then described, and examples given of their methods and of their value to staff and to patients Anæsthetics were given by trained nurse-anæsthetists, and Mr Anderson had seen all methods in use except the administration of chloroform Nitrous-oxide-oxygen was the most popular, but ethylene-oxygen was also being used extensively He referred in some detail, and with great admiration, to the neurological surgery done by Cushing Mr Anderson then described in fuller detail the work of the Mayo Clinic and some of the special surgery done there—cardiac, gall bladder, and lung surgery, exsanguination transfusion, and the investigations into liver function

PROPOSED SCOTTISH COLONY FOR MENTAL DEFECTIVES

An address on the permanent care of the feeble-minded was delivered by Lady Leslie Mackenzie at a public meeting held on December 10th Sir H Arthur Rose, chairman of the General Board of Control for Scotland, presided over the meeting, which, he stated, was held in connexion with a resolution passed recently by the Edinburgh Women Citizens' Association, to assist in raising money for a scheme to found a colony for the permanent care of the feeble-minded Lady Mackenzie stated that the subject of the permanent care of feeble-minded persons had been before some of her hearers for over twenty years The people of Glasgow had taken up this subject long before Edinburgh did, and for many years in Glasgow there had been special schools for feeble-minded children In recent years special schools for this purpose had been established in Edinburgh, and she wished to make it clear that the mentally defective child was simply a child whose brain was not fully developed and which unfortunately would never be fully developed It was important, therefore to train that brain, although they could not cure it of its deficiency In the special schools whatever way the teacher found to be best for using the intelligence of the child was adopted, and the teacher was given a wide amount of liberty in this respect Such things as garden ing, keeping pets, manual work, and doing odd jobs about the school were given to the children to do In Glasgow there were over 2,200 mentally defective children in the special schools, and in Edinburgh there were between 400 and 500 Although children were well looked after during their time in these schools they had to leave at the age of 16 as far as their mental equipment was concerned, and, therefore, unable to earn their living and to compete with the ordinary intelligent human being There was thus, unfortunately, a great tendency for many of the boys to get into trouble, to be convicted for stealing, and to pass from prison to street, from street to poorhouse, and so on The girls very often became the mothers of illegitimate children, and it was particularly important to prevent motherhood in these girls, and so to stop the reproduction of feeble minded people to a certain extent It was to meet the needs of the hundreds of children leaving the special schools at the age of 16 that the women citizens had come to the conclusion that they should take action The action they proposed to take was to collect sufficient funds to start one institution for the permanent care of the feeble-minded and it was proposed that this institution should take the form of a colony where the inmates could begin with school and then later go to workshop or farm, or some other form of occupation still within the colony

CENTRAL MIDWIVES BOARD FOR SCOTLAND

The report of the Central Midwives Board for Scotland for the year ending March 31st, 1924, has been issued At the annual statutory meeting Dr James Haig Fergus on was re elected chairman and Dr Michael Dewar deputy chairman The total enrolments of midwives for the year had been 458, which with 5,477 previous enrolments, completed a list on the register of 5,935 Of this number 2 584 had been admitted after examination, and it was believed that the number actually in practice was at the present time approximately 3,000 Four examinations were held annually, taking place simultaneously at examination centres in Edinburgh, Glasgow, Dundee, and Aberdeen, subject to a sufficient number of candidates having entered at each centre The number of candidates who appeared for examination during the year was 473 of whom 430 had passed These came from fifteen different institutions in Scotland at which midwives may be trained and of which four were Poor Law institutions During the period under review sixteen midwives were cited to appear before the Board to answer charges of malpractice negligence and misconduct and as the result of these charges the names of ten had been removed from the roll In seven cases the offence charged was that of failure to send for medical assistance in cases of inflammation of the eyes excessive bleeding abortion, rupture of the perineum, and failure to notify these cases Five women were suspended from practice for three months for general carelessness in treatment, failure to attend during the full period of puerperium or failure to keep records of pulse and temperature The Board had resolved that after January 1st, 1926, the period of training should be increased to twelve months, except in the case of nurses already enrolled in the registers of the General Nursing Councils or Scotland, England, and Ireland as having completed a training in general nursing, nursing of sick children or nursing of infectious diseases In these cases the period of midwifery training would be limited to six months

England and Wales.

UNIVERSITY OF LEEDS CELEBRATION WEEK

In 1874 the Yorkshire College of Science opened its doors with three professors and twenty four students, in 1877 a faculty of arts was founded and incorporated in the college in the following year In 1904 the college received its charter as the University of Leeds, Sir Nathan Bodington becoming its first vice-chancellor Of the four faculties of the present university—arts, science, technology, and medicine—the first is the largest, yet medicine preceded the university and the Yorkshire College of Science by a very considerable period chronologically, for in 1831 the earlier efforts to provide systematic medical training in Leeds reached their fitting conclusion in the establishment of the Leeds School of Medicine, which became part of the Yorkshire College in 1884 The teaching staff of the university includes 268 men and women there are forty-two departments of study and more than 1,600 day students The

jubilee celebrations during the current week commenced with a sermon by the Archbishop of York on December 14th, when he expressed the hope that some day a faculty of theology might be added In the afternoon of December 15th Sir Berkeley Moynihan gave a most interesting account of the progress of medicine in Leeds

SHEFFIELD JOINT HOSPITALS COUNCIL

The second annual report of the Sheffield Joint Hospitals Council, which has just reached us, gives an account of the very satisfactory progress made during 1923 in hospital finance In particular the "penny in the pound" scheme, of which we gave a detailed account on September 15th, 1923 (p 483), has received considerably increased support, many of the smaller establishments throughout the area having co-operated for the first time This scheme brought in £10,866, as compared with £3,957 in 1922 The income of the council showed a surprising increase over the preceding year, and amounted to over £102,000, it was £72,000 in 1922 This most satisfactory increase occurred despite the severe unemployment and depression in trade which characterized the year generally The report draws attention to the marked loyalty of every section of the city to the voluntary hospitals, and the happy co-operation that exists between the Joint Hospitals Council, the hospital boards of management, and the various individuals and institutions concerned The total number of available beds in the Sheffield hospitals is stated to be 856, and there are said to be 2,759 patients waiting for admission The Lord Mayor of Sheffield in the report urges, therefore, that further efforts should be made to meet the growing necessities of the city in this respect The in-patients during 1923 numbered 12,697, and of these 3,586 were unemployed and necessitous The total number of out-patient attendances was 386,552 During the year under review 495 patients were sent to convalescent and rest homes at a total cost of £2,864, paid by the Joint Hospitals Council The great variety and value of the work undertaken by the council is brought out clearly in the annual report, which will attract especial interest, since in some ways the methods adopted in Sheffield differ from those in favour elsewhere

MANCHESTER CHILDREN'S HOSPITAL

The Earl of Derby formally opened on December 8th a new home for nurses in connexion with the Royal Manchester Children's Hospital in Pendlebury Accommodation is provided for sixty nurses in a spacious and well furnished recreation room, but at present only twenty-nine bedrooms are available Provision has been made by the architect for the opening of another wing in a few years, if the necessary money can be collected This would render it possible to house all the nurses, apart from those actually living in the hospital itself Up to the present an isolation block has been used as a nurses' home, but the new building will now enable this block to be available for its original purpose in case of emergency Of the £17,000 required for the new building £10,000 has already been received Lord Derby paid a warm tribute to the valuable and unselfish services rendered by the nursing staff, and referred to the important work carried on in the hospital Since the ground on which the home is built overlies a coal mine, the whole site has been covered with strong reinforced concrete, to minimize so far as possible any danger of subsidence

EXPENDITURE ON TUBERCULOSIS AND OTHER SERVICES IN LONDON

The Ministry of Health has asked the London County Council to forecast its expenditure for the year 1925-26 on the treatment of tuberculosis, the diagnosis and treatment of venereal diseases, and maternity and child welfare services The forecast as regards tuberculosis is £135,650, which is £15,000 more than the estimate for the present year For venereal diseases the Council's proportion of the estimated expenditure to be apportioned between the Council and neighbouring local authorities is £91,565, which compares with almost the same amount for the present year Both these figures are exclusive of sums of £20,000 and £10,000 which it is proposed to include in provisional amounts to cover possible developments of the work in connexion with the services mentioned The net expenditure on maternity and child welfare services is estimated at £10,190, as compared with £9,664 for the current year.

Correspondence.

EPSOM COLLEGE

SIR,—With the approach of Christmas, a season in which humanity at large relaxes its purse-strings, I ask your readers to bear patiently with me while I expound to them the work and the needs of one of the great medical charities

The Royal Medical Foundation of Epsom College exists (*a*) to give pensions to fifty aged or disabled medical men or their widows, and (*b*) to provide, free of charge, a good public school education, together with clothing, maintenance and pocket money, to fifty sons of deceased or disabled medical men

The Medical Foundation, so far as it is educational, is part and parcel of Epsom College, which is a public school open to all, but aiming especially, according to the intentions of its founder, at affording to the sons of medical men generally a school education at as near cost price as possible

Generous benefactions have augmented the value of many pensions and increased their number, so that last year the College bestowed no less than 166 That alone alleviates a sensible part of the destitution that befalls the unlucky in our profession as in any other But the part relieved is not nearly large enough, and to do much more much more money is needed

Perhaps, however, it is our educational work that awakens the warmest and widest sympathy There is very keen and widespread competition for the Foundation Scholarships, which have given to so many needy boys a start in life, open to them in no other way The expenditure on these has been greatly increased owing to the circumstances of the war and growing educational needs

To those who may catch sight of this letter I appeal to set it aside for perusal after a satisfying Christmas dinner, to sit down then in an easy chair with a pipe, and with closed eyes to conjure up before their minds a vision of their own wives, left widows in need, and suppliants to human kindness for the upbringing and perhaps the very bread of their own necessitous children Then let them at once, before the image has dissolved in the welter of work, draw up to their table and write us a cheque for such a sum as the spirit has moved them to give I warrant that the whole service shall add to, not detract from, the gladness of their Christmas festivities

Commercial travellers, haberdashers, and others provide tens and hundreds of thousands of pounds yearly for their needy, medical men give us less than four thousand for theirs At present one medical practitioner in sixteen helps us, if all would help with half a guinea yearly, or, better still, because easier of fulfilment, if half would help with one guinea yearly, we could multiply our present income by six In five years the Medical Foundation, at its present dimensions, would be permanently endowed, and all wearisome begging would be at an end, to the great advantage of the College With like support for a further five years we could go forward confidently to make our benevolent work commensurate with the full needs of the profession, and our school, with due regard to the intentions of our founder, second to none and an example to all, and an object of justifiable pride to the whole profession So trifling an individual sacrifice for so immense a common good cries aloud for its accomplishment!

Let me first lay my own gift on that altar by trebling my own subscription, so that I may earn the right to appeal to those who already help us and can do more to do it, and to those who do not help as yet to come to our aid

Cras amet qui nunquam amavit, quique amavit cras amet

One guinea annually, or a single donation of ten guineas, makes a governor and gives ten votes at each election in June of foundationers and pensioners, and each additional guinea annually gives ten votes more Voting papers, with details of candidates, are sent in advance to every governor Seldom a list that makes no direct appeal sometimes it will be the voice of a dead friend asking help for those he has left behind

Please send a subscription or donation to the Secretary of Epsom College, 49, Bedford Square, London, W.C.1, who will be glad to give any information, and welcomes personal visits at any time.—I am, etc.

RAYMOND CRAWFURD, M.D.,
Chairman of the Council of Epsom College.

49 Bedford Square, W.C.1,
Dec. 3rd.

FREUDIAN DOCTRINE

SIR,—I have read with much interest the article in the JOURNAL of December 6th (p. 1063) which is headed "An attack on Freudian doctrine," and includes a summary, by Protes of Sollier, of the proceedings at a conference on psychology held at the Institut des Hautes Etudes de Belgique, which was published in *Le Scalpel* of October 4th and October 11th this year.

In the course of this conference the discussion of psychoanalysis played, as the title of the article in the JOURNAL implies, a very important part. So far as I know no discussion of this subject of similar weight and authority has taken place under the auspices of any medical or scientific body in Great Britain. Yet the principles and practice of psycho-analysis are becoming widely known among the laity, and are constantly being referred to by the public press and in the pullulating literature of fiction is the new "psychology." They have also been received in the form of speeches or papers by a conference of Modern Churchmen and at a meeting of the Royal Anthropological Institute, without discussion in the course of this year.

I do not ask you, Sir, to open your pages to any such discussion as I have in mind, but would merely suggest that you might be able to invite members of the medical profession, as well as psychologists generally to say which or no such discussion would be desirable and practicable. I may add that two considerable attacks on Freudian doctrine have been published during the last two years in London, neither of which has been replied to by any prominent advocate of this doctrine.—I am, etc.

BRYAN DONKIN.

London, W.9, Dec. 11th.

** We are prepared to receive replies to the suggestion contained in the last paragraph of Sir Bryan Donkin's letter but cannot open our columns to the discussion of Freudian doctrines generally.

THE CENTRAL PRACTITIONER AND THE MATERNITY SERVICE

SIR,—Let us hope the reasoned appeal of Dr. John S. Fairbairn, whose opinion is of great value that this controversy may not develop into something like a wrangle between the general practitioners and the obstetric experts may bear fruit. But I have certain doubts. The attacks of his specialist friends have been too bitter and provocative I am afraid for anything like a truce.

Dr. Fairbairn's call upon the practitioners to withhold the courage from the shrinking hides of the specialists is stirring enough. The present correspondence was initiated by Dr. A. Louise McIlroy who made certain statements and laid down certain suggestions. This was followed by a letter from Dr. Agnes Hill Nicoll who supported and elaborated Dr. Louise McIlroy's communication. It is fair to assume that neither of the writers has much experience of general practice, at any rate in wide country districts. They barely disguised their contempt for the general practitioner as an accoucheur but they went out of their way to boast thoroughly the highly skilled body of specialists' duties as midwives and implied not obliquely that unskilled midwifery was directly due to the ignorance or incompetence of certain wretched practitioners. Listen to Dr. Agnes Nicoll in your issue of October 11th: "I would add my testimony as to the results of unskilled midwifery in producing the chronic ill health of many mothers who attend child welfare clinics." It is presumed, naturally, that general practitioners are chiefly, if not solely, responsible for the prevalence of puerperal sepsis.

One hesitates to retort upon these ladies especially as I am of opinion that their knowledge of general practice is rather limited. It is one of the inevitable consequences of the admission of women into the medical profession, who are excellent students and usually glib in examinations, that they find themselves rather in the air when the undertake general practice, and so they incline to some sort of officialism and favour jobs under an authority. Of course, I am not out to attack medical women, and least of all two such distinguished women though I am inclined to view their faith in specialization and institutional treatment, and all the other potential aids of licensed officialism, as a remedy for the present alleged parlous condition of obstetrics, as being rather pathetic. But I do protest against the constant iteration of specialist, individually and collectively, that puerperal sepsis usually arises in general practice and should be laid at the doors of the family doctors. There is not the slightest evidence for such a misconception that I am aware of.

The question now arises, Why is there so much puerperal septicæmia in these days of improved technique and general and special knowledge? In my opinion the reply is not only simple but quite obvious. I ever since the increased employment of midwives the progress of midwifery in general practice has halted and gradually diminished. Owing to many causes maternity work has become unpopular in general practice. It is uncertain the work is also sometimes extremely risky one and irregular it often involves night work and sometimes demands great skill and pluck and initiative at the very time when one's vital energy is at the lowest ebb and it is also quite unremunerative in proportion to the time and skill employed. Beyond that there is another factor in the disinclination for obstetrics which Dr. Louise McIlroy artfully mentions—namely, the lamentable deficiency of the clinical training of medical undergraduates. It is not only lamentable it is nothing short of a national scandal! Dr. Fairbairn may endeavour to defend his own class in your columns but it is notorious that in the universities and medical schools the amount of time and attention given to practical midwifery is grossly insufficient. I have employed assistants and locumtenents recently qualified whose knowledge of the art and practice of midwifery was almost elementary.

In the old days a man went into general practice often as an assistant with an experienced general practitioner who did all his own midwifery. After an uncertain period of what was really advanced apprenticeship he was bound to learn a good deal about normal and abnormal labour. There was a period of some mental distress and many alarms and qualms, and he either emerged a sound obstetrician or else if ever after dreaded the very name of obstetrics. Nowadays a medical practitioner may have a large and valuable practice and scarcely ever be called upon to attend a confinement. Normal cases are taken off his hands by the midwives who call in an expert when in difficulties and his better-class patients seek sanctuary in a nursing home or some other obstetric institution. Should he ever essay a maternity case he finds himself sadly lacking in that experience and knowledge that can only come from constant practice. The consequence is that the modern family doctor is less able to undertake obstetrics than his predecessor, and the general level of obstetric achievement is lowered.

That such a condition of affairs is other than good for the profession and the public is pretty evident.

And what is the remedy? First of all give the future medical practitioner a sound grounding in practical midwifery. It is nonsense to say there is no time or opportunity for this before now I have taught a raw student how to deal with practically every complication he is likely to see in general practice in a very short time. Obstetric experts and specialists are too prone to magnify their art and the difficulties of complicated cases. My old chief who thoroughly knew his business, used to say that there was less skill required than in cleaning a clock or tying a trout fly. Given a sound technique and a fair training with plenty of practice, all the difficulties mentioned in such a textbook as Fairbairn's *Encyclopædia of Midwifery and Diseases of Women* are quite easily vanish, and the practitioner can confidently undertake almost every case he is ever likely to come across.

I consider the modern tendency to banish midwifery from general practice, and so to create a monopoly hatched between the midwives and the specialists—a not permicious one—and I speak after an experience of some four thousand cases

which embraced practically every kind of difficulty, from simple forceps extraction to Cæsarean section I never see puerperal sepsis, and I have not yet had occasion to call in another medical man—except in rare cases to give an anæsthetic I hold that the home is the most natural place for the confinement, and that the family doctor is the best accoucheur in the great majority of cases True, there may be exceptions in large industrial areas or where the house is unduly insanitary But should obstetric institutions come into vogue universally I can see no reason why the general practitioner should not conduct his own cases There may be some individuals who feel inclined to delegate this duty to others, for reasons of convenience or want of confidence Such an attitude is bad for doctor and patient The craze for team work and specialization in every department of medicine is working havoc with the general level of the practitioner's work He is fast becoming a sort of glorified drudge, whose activities are confined to first-aid and signing certificates for an exacting authority The openly expressed contempt of the one-sided experts will very soon extend to the general public if it has not already done so It is up to the general practitioners to speak for themselves and to stay any further excursions into their domain

I have an opinion, founded upon full knowledge, that the *statistics of a well conducted general practice* compare more than favourably with those of even the best institutions Not long ago a midwifery case, previously successfully delivered at home by the family doctor, was removed into an institution at the end of the eighth month of pregnancy on account of a justo-minor pelvis She died on the third day of the puerperium! Personally, I should prefer the services of a first-class general practitioner to any specialist I have yet seen at work, provided the case was one which did not require much cutting There should be no rivalry between specialist and practitioner certain surgical and obstetrical cases are of such a nature as to demand the highest skill of the expert in a suitable institution In midwifery practice such cases are extremely rare, and when they do occur the well trained and experienced practitioner is infinitely better able to deal with them than any midwife

One cause of infection in women of the industrial class treated at home I have not seen mentioned, and that is a want of personal cleanliness of the pregnant woman I had to fight a battle royal, I remember, when I first insisted that every woman must have a warm bath with plenty of antiseptic soap at the beginning of labour The effect of such an elementary precaution was really marvellous Rises of temperature that were too frequent practically disappeared I am of the profound opinion that the great majority of infected cases are due to preventible causes They arise from infection due to a lapse on the part of either the midwife, the doctor, or the woman herself—I am, etc,

Holmsley, Yorkshire, Dec 8th ALEXANDER BLAIR, M D

PUERPERAL SEPSIS

SIR,—I consider that Dr Stavely Dick has struck the keynote (December 6th, p 1079) in respect of the diagnosis, prognosis, and treatment of fever associated with the puerperium

I may add that if the blood, the urine, and swab are found to be sterile a *dose of calomel will quickly clear up* matters, as in this case the temperature, etc, are most probably due to an intestinal toxæmia If, however, organisms are found, the *importance of an early diagnosis* cannot be overmuch stressed

I should place the *treatment and early diagnosis of* puerperal fever on the *same footing* as that of pneumonia To wait for the classical signs is simply courting disaster In the latter disease early diagnosis, including that of the organism, is all-important

Shortly, my method of procedure is as *follows* An early sputum examination and the immediate injection of a stock vaccine of the *like organism* whilst an autogenous is being prepared As long as there are signs of improvement I never repeat the vaccine Too early repetition is, in my opinion, the great mistake *in vaccine therapy* I keep my patient on water for at least forty-eight hours, allowing only fruit juices and an occasional stimulant if necessary My experience in pneumococcal pneumonia is that one may confidently expect a crisis in from twelve to thirty-six hours if the above precautions have been taken

It would be of great interest to know if any of your readers have had experience of immuno-transfusion in either of the above diseases In a case of ulcerated colitis in which I had an immuno-transfusion performed my patient died within an hour with all the symptoms of an anaphylactic shock This case, however, was already of three months' duration—I am, etc,

Plymouth, Dec 14th W LANG-HODGE

SIR,—In your issue of December 6th (p 1079) Dr Stavely Dick relates *some of his experience in dealing with this* disease I feel that Dr Dick, and perhaps others among your readers, may be interested in the following results of fifteen cases which were investigated in the laboratory of the Women's Hospital, Birmingham In each of this series the presence of a septicæmia was proved by obtaining from the blood stream a pure culture of a hæmolytic streptococcus

Four of these cases recovered, all of which were treated with an autogenous vaccine Of the fatal cases—eleven in number—three only received autogenous vaccine, and all three were admitted to hospital after more than a week's illness with pyrexia In seven out of eight of the *remaining* cases, death occurred within forty-eight hours of admission, and thus administration of an autogenous vaccine was precluded In one fatal case a vaccine was prepared but was not administered, and at autopsy a recent vegetative mitral endocarditis was demonstrated, engrafted upon an older inflammatory lesion of this valve—I am, etc,

Edgbaston, Birmingham Dec 8th REGINALD G ABRAHAMS

TONSILLECTOMY

SIR,—I have read the correspondence under the above heading with some interest That enucleation of the tonsil, when necessary, is to be preferred to tonsillotomy must be the opinion of a large majority of laryngologists, but if it is to be *maintained* by those who habitually practise dissection that no other method is surgical or thorough, then I must decline myself to be among those who disagree I do a large number of these operations in the course of the year, and I do not suppose that more than 2 per cent are cases for dissection The important point that must not be lost sight of by the operator is that primary and secondary haemorrhage is invariably due to the fact that a portion of the tonsil has been left behind This is the underlying danger of tonsillotomy—I am, etc,

J A GIBB

Maidstone, Dec 8th

SIR,—I am surprised to see surgeons still discussing the comparative value of tonsillotomy and tonsillectomy And I am so convinced of the superiority of the Beck-Sluder hidden-wire instrument that I feel impelled to bring it again to the *notice of British surgeons* It meets all the requirements demanded by Dr Sichel (BRITISH MEDICAL JOURNAL, November 15th, p 926), provided one understands that the tonsil must be pushed by the forefinger into the foramen A little knack is needed, and the tonsillectomy is beautifully clean and free from injury to surrounding tissues The only cases in which it fails are those in which the tonsils and fauces are firmly matted by old adhesions—I am, etc,

Atlanta, Georgia Nov 29th ALEX W STIRLING, M D Edin

SAUCE FOR GOSLINGS

SIR,—Surely it is getting high time for the collective opinion of the profession to express itself with some approach to definiteness on the question of medical publicity The proceedings of the General Medical Council and its judgements expose us, not altogether unnaturally, to a good deal of lay ridicule, not untinged with contempt Yet we are not in a position to blame the Council, seeing that we, like it, have so far formulated no accepted principles for our own and its guidance

Small men are hailed before the Council, and either patronizingly censured or removed from the ranks of the profession for two-guinea contributions to the weekly press, whilst the hundred-guinea contributions of their big brothers to the daily press are tolerated without comment. I could quote examples by the dozen. Only to-day I picked up in a bookshop a new popular work, with the not too dignified title *How is Your Heart?* clothed in a "jacket" as sensational as the title. The name and qualifications of the author are bla-zoned on the cover, the title-page, and the wrapper. And the book is prefaced by an introduction from the hand of one of our medical baronets in which he informs the public that Dr —— (the author) has made a special study of the particular subject under consideration" that his experience in the study of heart affections is very large, that he is thoroughly versed in his subject, and familiar with all its principles, and that he possesses a wisdom that is all too rare." It will be indeed surprising if many dozens of readers, when they come to chapter ten, which deals with "Early heart signs that should take you to your doctor," do not straightway look up in their telephone directory or other work of reference the address of this well-experienced man.

I happen to take the rather priggish view that the interests of the public must override our professional interests when they conflict. And therefore I am not quoting these extracts for the purpose of hot-tish criticism, but I am perfectly sure that if any of us had ever thought to write for the lay press an article on any special branch of medical practice, and allow it to be prefaced either editorially or by a medical friend with boosting announcements of our prowess and experience in this particular branch, we should soon find ourselves in the medical dock. Sauce for the goslings should be sauce for the ganders. Whatever laws we lay down should be such as can be defined and expressed in words. Having been laid down, the observance of the laws should be imposed with genuine impartiality on lay physicians and the humble medical journeyman alike.—I am, etc.

London, E.1, Dec. 6th. HARRY ROBERTS.

THE MADRAS GOVERNMENT AND INDIGENOUS SYSTEMS OF MEDICINE

SIR,—In my letter published in your issue dated October 25th I wrote: "The recommendation for the cutting down of the diets have been made on the advice of an impecunious officer, who, whatever his admirable qualities may possibly be, has, I believe, no qualification that would entitle him to registration in Great Britain." A Madras correspondent has kindly written to point out to me that the I.M.S. qualification of Madras University held by this gentleman was *formerly* registrable. I at once communicated with the Registrar, General Council of Medical Education and Registration of the United Kingdom, who has kindly given me the following information:

"The L.M.S. Madras could be registrable on May 24th 1933 when the Council drew the attention of the University to their resolution that the course of study should occupy at least five years and stated that in such circumstance they could not accept the Licence with its then curriculum of four years except in the case of those who commenced study before January 1st 1892. Further requests for the recognition were made in 1915 and 1917 and were both refused."

I have also ascertained from the same source that as this gentleman qualified in 1890 he was actually eligible for registration, but that "he has never appeared upon the *Medical Register* here." I regret that even in so small a detail I should have been incorrect, and, though the error does not in the least affect my point, I desire to do away with any shadow of want of accuracy. May I therefore ask the favour of your inserting this letter in the JOURNAL?—I am, etc.,

R. H. ELLIOT,
Lieut.-Col., I.M.S. (ret.).

London, W., Dec. 14th.

MULE-SPINNERS' CANCER

SIR,—It would be unfortunate if anything I said or omitted to say in my paper conveyed a wrong impression regarding Mr. S. R. Wilson's observations. I accept unreservedly his statement that he was aware of the association of scrotal cancer with mule spinners as far back as 1906, and that he convinced his colleagues in Manchester of the truth of his thesis, although Mr. Morley in 1911, in the paper to which he refers, did not mention this striking association. In view of the high incidence of the disease we can join with Mr. Wilson in his regrets that circumstances prevented the publication of his findings for so many years during which, had the knowledge been more widely disseminated, steps might have been taken to prevent its occurrence. As nothing appeared in print before November, 1919, or was known even to the factory inspectors, I think I was fairly accurate in stating that "no one until within the last two years *seemed* to have known."

Please give me leave once again to express my great appreciation of the value of the discovery of mule spinners' cancer by Mr. Wilson and his colleague Mr. Southam, and to say that if by further endeavours they are instrumental in preventing it as they quite well may do, they will have done a good service to medicine.—I am, etc.,

ARCHIBALD LEITCH.

Cancer Hospital Research Institute, London, S.W.3, Dec. 15th.

DIAGNOSIS OF CANCER OF THE THYROID

SIR,—May I correct a statement attributed to me in the JOURNAL of December 13th (p. 1113) in the report of the discussion on "Diagnosis of cancer of the thyroid"?

The final sentence reads: "He made a strong plea for the removal of all adenomata of the thyroid since eventually they caused pressure or toxic symptoms or became malignant." This report contains two grave errors as neither the statement nor the reason given for it is correct.

To remove all adenomata would be unnecessary for the patient and discreditable to the surgeon. What I said was that because some adenomata ultimately cause pressure symptoms, because some eventually become toxic, and because 3 per cent. of the cases which had come to operation—not 3 per cent. of the cases seen—had been proved to be malignant, therefore adenomata of the thyroid could not be regarded as entirely innocuous tumours, also that a woman has the right to ask for the removal of a tumour which is large enough to be a disfigurement when the enucleation of an adenoma does not deprive her of any normal thyroid tissue.—I am, etc.,

T. P. DUNHILL.

London, W.1, Dec. 15th.

Medico-Legal.

VERDICT OF MANSLAUGHTER AGAINST A MEDICAL MAN

Press Association.

At the Central Criminal Court on December 12th Dr. Percy Bertram, a medical practitioner of New Cross Road, was found guilty of the manslaughter of the wife of a labourer named Harding, living at Deptford, and Mr. Justice Shearman sentenced him to six months' imprisonment in the second division.

Mr. Percival Clarke, Mr. H. D. Roome, and Mr. W. Bentley-Purchase prosecuted for the Director of Public Prosecutions, and Sir E. Marshall Hall, K.C., and Mr. Arthur H. Davis appeared for the defence.

It appeared that the accused was called in to attend Mrs. Harding in her confinement at 10 p.m. on July 23rd. Labour and the prosecution alleged that her death was caused or accelerated by his failure—in the circumstances which arose during the confinement—to call in a second medical practitioner and to arrange for an immediate operation. His omission to take these steps was it was contended due to his desire to prevent anyone from knowing that he had pulled away the uterus during the confinement. The accused continued to attend Mrs. Harding at her home until July 26th, when he sent her to hospital, and she died at the hospital on July 30th.

Sir Bernard Spilsbury, in the course of his evidence for the prosecution, expressed the opinion that if the woman had been operated upon she would have had some chance of surviving, and that she would have been fit for an operation before she was removed to the hospital.

Dr. J. Bright Banister, obstetric physician to Charing Cross Hospital, giving evidence for the defence, said he only knew of two of her cases where the uterus had been removed, and in both of them no operation was performed—in the one case because the patient died on reaching the hospital, and in the other case because the patient died within thirty minutes of arrival at the hospital. Therefore in his opinion the conduct of the accused in keeping the patient lying at her house for nine days without sending her to hospital for an operation could not be said to have accelerated her death. Her chance of life was so small as almost to be negligible. He (the witness) would have considered the

patient's removal to hospital, and in his opinion, removal would have destroyed any chance of life Some time during the five days following the confinement there was just a chance that she could have been removed and have had a successful operation He could not say there was any more favourable moment at which she could have been removed than the moment at which she had been removed The doctor in attendance must always be the judge Her chances of life were as good left where she was as if she had been operated upon If it were a complex presentation, as the accused said it was, then it was a most difficult affair

Dr Hubert Roberts, senior obstetric surgeon to Queen Charlotte's Hospital also gave evidence for the defence He said it was a very difficult and dangerous case, and as the patient was suffering from acute shock nothing more could be done beyond leaving her at rest in bed In cross examination, he agreed that it would have been advisable for Dr Bateman to have called a colleague into consultation

Dr Bateman, in his evidence, said that when he was called in the nurse who was in attendance said the deceased woman had had pains for two days before He made an examination with his hand and he felt the head of the child He gave chloroform to the patient and applied instruments but they slipped at once as it was a transverse presentation He immediately desisted from the use of instruments and decided to use a treatment known as manual version He realized that it was a difficult case, but if he sent the woman to an institution then the probabilities were that the child would be born dead He therefore put his hand in the vagina to ascertain the position, and he found the feet When turning the body of the child there was considerable difficulty because its head was in the pelvic cavity, firmly impacted He continued the treatment for over an hour, and finally succeeded in delivering the child feet first in the usual way He then attended to the patient again for the purpose of bringing away the after birth He put his hand into the womb and brought the afterbirth away quite easily without the use of any force at all The nurse was standing by with a bowl, and he put the afterbirth in the bowl without looking at it very carefully, as the patient had collapsed, and it was necessary for him to attend to her immediately The room was very badly lit at the time by one broken incandescent gas mantle, five or six feet from the patient, and it would not have been possible to make an examination of the afterbirth without looking at it very closely and carefully, which he had not time to do He felt the woman's pulse and found that it was absent In consequence he gave her a hypodermic injection of strychnine, after which she rallied slowly It was untrue to say that after the child was delivered he made preparation for departure After the woman had rallied both the nurse and himself placed a hand over the abdomen of the patient to see if the uterus was contracting but to their surprise they neither of them were able to find it The nurse then brought to him the bowl in which the afterbirth had been put and he then looked at it carefully and to his surprise found the uterus also He realized that when he had extracted the afterbirth the uterus had come away with it The patient was in a collapsed state and quite unfit to be removed, though he knew that an operation would be necessary to save her life and that the operation should be performed as soon as possible He looked at the patient but came to the conclusion that she would never be in a fit state to survive the operation, and he had to decide immediately what was the best course to adopt He did not wish to shock the relatives, and, consequently, he told the nurse to say nothing to them about the fact that the uterus had come away The nurse wrapped it up and he took it away with him to his surgery He gave instructions to the woman's husband not to move the woman, being of opinion that any movement would be fatal and would start haemorrhage On his arrival home he showed the uterus to his partner Dr Carroll Twice a day afterwards he visited the patient and never was she well enough to stand an operation It was because the husband said the family were all worn out that he ordered her removal to hospital on July 28th

In reply to Mr Roome Dr Bateman said that had the woman died he would have given a death certificate

And no one would have heard of the matter?—Probably not

That is what you wanted I suggest?—That is not a fair question I did not want anything hid I probably should have consulted another medical man as to the procedure I should have taken

In the course of his summing up the judge said that a jury should only convict a doctor of causing death by negligence if he did something which no ordinary skilful doctor should have done

The jury were in retirement over an hour before giving their verdict

Mr Justice Shearman, in sentencing the accused, said he appreciated what a crushing blow to a professional man the mere conviction must be

The propriety of appealing is, we are informed, under consideration

Universities and Colleges.

UNIVERSITY OF OXFORD

THE following candidates have passed the Final Examination for the degrees of B M , B Ch in the subjects named

Materia Medica and Pharmacology D A Abernethy F J Bach A V Clemmey C R Croft T L Davies J H Ferguson E L Fothergill W H Hudson T M Ling D Lurie S Segal C W Simpson A G Wilson E M Wright Grace Batten Rosalind V Carruthers Margaret A L Herbertson Olive H Lister Irene M Titcomb *Pathology* D A Abernethy F J Bach R H B Bettington W B Boone C Charleson J C K Chilcott J L Cox G H Crisp C R Croft J A Eyres C W Fleming J N C Ford A T Fripp K A Hamilton S Harris H O Hopkins S Howard J S Jerome T M Ling C W Mackenzie R G Mathews E L Newell W F Howson Ray F J Sale J W de W G Thornton G P Thorold O R Tisdall E C Whitehall Cooke A L Wilkinson D O Williams Alice D K Peters *Forensic Medicine and Public Health* C E G Beveridge C P Blacker H A Byworth T A J M Dodd A T Fripp H L Harding J S Jerome M J W Minshull E L Newell J de la M Savage H N Stokoe R A Walsh D O Williams Mathilde E F Bugnion Ella J Cockram *Medicine Surgery Midwifery* M Mel Baird R J Brocklehurst T A J M Dodd H L Harding J R B Hern T B Hodgson P H Martin J D Mills M J W Minshull A W L Row H N Stokoe B E Tompson Mathilde E F Bugnion

UNIVERSITY OF LEEDS

AT a congregation held on December 13th the following degrees were conferred by the new Vice Chancellor, Dr J B Baillie

M D—G F Walker (with distinction) Ella M Hickman

M B , Ch B—*Marjorie E Knowles †Dorothée M B Gross †S K Sledge C H Ackroyd E E Blomfield Kathleen Boddy G Chambers Florence Cusworth G K Hatton H Hartley H A Hellewell F H Lodge W Murphy S Nagley R S Pyrah G D Rai G Rosemont F T Ruston Ann Sugden K A Turner

* With first-class honours † With second class honours

The William Hey Gold Medal for 1923 for the most distinguished graduate of the year was presented to G F Walker, who graduated M B , Ch B with first class honours in that year

The William Hey Gold Medal for 1924 and the West Riding Panel Practitioners' Prize in Medicine have been awarded to Marjorie Llaine Knowles

At the close of the ceremony the Vice Chancellor, who was warmly received by the students and those members of the general public who were present, gave a short address to the graduates In doing so he said he thought he might be departing from precedent His brief address, however, was so charming and so full of wisdom that everyone felt that a much greater breach of custom would have been amply justified

VICTORIA UNIVERSITY OF MANCHESTER

THE Council has accepted with regret the resignation of Dr W H Wood, lecturer in anatomy and tutor to the Faculty of Medicine, on his appointment to the Derby Chair of Anatomy in the University of Liverpool

Drs A L Barclay B A McSwiney, and B J Ryrie have been elected members of the Board of the Medical Faculty

ROYAL COLLEGE OF SURGEONS OF ENGLAND

AN ordinary Council meeting was held on December 11th, when the President, Sir John Bland Sutton, was in the chair

Fellowship

The Court of Examiners reported that at the recent examinations for the Fellowship 105 candidates presented themselves, of whom twenty seven were approved, including three (M A Lautre D Levi and C Stirton) who had not yet complied with the regulations Diplomas were granted to the following successful candidates as well as to Mr Arthur J Gardham, who had now attained the required age of 25 years

Arthur Rocyn Jones Anthony Blackstock Angus Hedley Whyte Frederick Cecil Wray Capp Bernard Warren Williams John Taylor Blackburn Haridas Jamnadas Bhatia Alexander Ernest Roche Frederick William Widgery Daryll Cedric Corry David Howard P[illegible] William Stewart Duke Elder John Dreaper [illegible] Brown Edwin Thomas Cato Charles Mills Greenslade Raymond Valentine Hennessy Alan Edward Lee George Dixon Fisher McFadden Charles Harwood Osborn Michael Joseph Smyth Hubert Wallace Symons

Membership

Diplomas of Membership were granted to the following

Margaret I B Cowling May H Elmitt and C J Polson

Licences in Dental Surgery were granted to ninety eight candidates

A report from the Board of Examiners in Dental Surgery was approved and adopted—that the regulations be modified so as to provide that a student who fails in any subject of the examination must produce a certificate that he has been "working in a dental school to the satisfaction of the dean for a further period of three months"

Tuft's College Dental School, Boston, Mass , U S A , was added to the list of institutions whose degree of D D S is accepted as exempting a candidate from the preliminary science examination and as admitting him to the first and second professional examinations on production of the certificates of study required by the regulations of the College

A report on the proceedings at the annual meeting of Fellows and Members was received

Mr H S Pendlebury was re elected a member of the Court of Examiners

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

AT the annual meeting of the Royal College of Physicians held on December 4th, Dr George Lovell Gulland, C M G , was re elected President for the ensuing year The other office bearers were re elected also

He cleared up many of the difficulties in the interpretation of ovarian pregnancy, in the real significance of the occurrence of Neanderthaloid characters in aboriginal Australians, and in analysing the complicated factors of spinal shock following transverse section of the spinal cord The first of these three noteworthy memoirs was published in the *Journal of Anatomy* in January, 1922 The special value of the case of primary ovarian pregnancy was due to the early period of development and the clearness of the evidence in demonstration of the fact that the ovum was fertilized as the closing coagulum was formed in the mouth of the Graafian follicle and proceeded to develop in the connective tissue in this situation, embedding itself *ab initio* outside the growing corpus luteum of pregnancy The lucidity of the account of this specimen and the interpretation of its complexities afforded the first indication to the *anatomical world at large that a new John Hunter had arisen*

The results of the experimental work that he carried out in collaboration with Mr N D Royle between October, 1920, and July, 1921, were not published until this year ("The symptomatology of complete transverse lesions of the spinal cord," *Australian Journal of Experimental Biology and Medical Science*, vol i, 1924, p 57) By means of an ingeniously devised series of experiments he courageously attacked a difficult problem which had taxed the skill of many of the best experimental physiologists and clinical observers of Europe and America In particular he addressed himself to the task of deciding whether or not vascular disturbances played a part in determining spinal shock He showed that the variations in the ultimate results after section of the cord cannot be wholly explained by release of function alone There may be combined with release of function (due to section of the conducting pathways), vascular changes leading to rapid degeneration, or a temporary stage of hyperexcitability of the nerve cells The experience gained in this preliminary investigation was destined to prove of far-reaching importance when, in 1922, Hunter and Royle embarked upon the still more difficult task of cutting the Gordian knot of controversy regarding the sympathetic innervation of striated muscle and the central control of muscular tone But before undertaking this work Hunter spent eighteen months in Great Britain, Europe, America, and New Zealand, getting into touch with the medical schools of the world He went first to his former master, Professor Wilson, in Cambridge, who magnanimously allowed us at University College, London, to have the privilege of Hunter's stimulating help for a whole year During that time he occupied the position of an honorary lecturer, and he taught and carried on research, gave addresses to various societies, studied clinical methods (especially neurology) in London, as well as in France, Holland, and Germany, and visited and made himself familiar with the methods of anatomical departments in most of the British and many of the Continental schools

He carried out an important research upon the oculomotor nucleus of Tarsius (*Brain*, 1923), which, taken in combination with the results obtained by Brouwer, sheds important light upon the problems of human evolution He made an intensive study of the fossil remains of men, and devoted particular attention to the Piltdown and Rhodesian remains in the British Museum He devoted much time and energy to the problems involved in the reconstruction of the Piltdown skull, and showed that when the occipital region is properly reconstituted and orientated it presents a much closer analogy to the condition found in the newborn African anthropoids than does any other human skull By demonstrating that there is no disharmony between skull and jaw he has eliminated the chief factor in the controversy that had been raging for ten years before his work was done His monograph on the Piltdown problem, written in 1922, has not yet been published

During the short time he spent with Dr Ariens Kappers in Amsterdam he completed an investigation on the forebrain of apteryx (*Koninklijke Akademie van Wetenschappen te Amsterdam*, 1924), for which he was awarded the M D degree of the University of Sydney and the University medal On his way back to Australia he spent nearly three months visiting American and Canadian medical schools and not only acquired a knowledge of the scientific workers and their methods, but also rendered a great service by expounding in lectures and demonstrations the meaning of recent anatomical and neurological work in England In particular he did a great deal toward making Dr Henry Head's work on aphasia understood On his return to Australia he was made full professor of anatomy, being given the Challis Chair which Professor Wilson had formerly occupied, and he set to work to introduce the far-reaching changes incidental to the restoration of histology to the department of anatomy With the experience gained in his pilgrimage abroad he came to exercise an influence in the medical school and University, he was worshipped by the students and trusted implicitly by his colleagues

But the heavy work which these things involved did not prevent him from embarking upon a new and most formidable task—the experimental investigation of the problems of muscular tone, the solution of which had hitherto defied the leading physiologists and neurologists He attacked this intricate conundrum with confidence and courage His experimental work upon the effects of section of the spinal cord gave him technical experience and practice in observing the effects of lesions of the nervous system, his association with Professor Kulchitsky at University College had given him an exact and certain knowledge of new facts relating to the sympathetic innervation of striated muscle which were of fundamental importance in the attempt to solve his problem, and his experience of the work at Queen Square, the researches of Dr Henry Head, and Professor Stopford's work in Manchester, strengthened his assurance boldly to attack the problem He had explored the field of neurology and acquired the wider vision, he had acquired the experience of solving his own problems and of seeing other people solve theirs, he was ready to defy armchair critics and boldly to attempt the solution of the enigma of muscle tone

For several years Mr Royle had been endeavouring to devise some means of alleviating spastic paraplegia He had tried the usual surgical procedures on human patients, and by experiments on animals tried to discover some new operation, without much success He put his difficulties before Hunter on the latter's return to Australia Hunter showed him some of Kulchitsky's histological preparations, which revealed quite clearly that, contrary to the opinion expressed by Boeke and Aghduni, the sympathetic fibres to striated muscle did not go to the same muscle fibres as the medullated nerves He suggested that they should cut the [illegible] to an animal's limb and study the result [illegible] that section of the sympathetic did not destroy tone, nor even necessarily reduce it The change in tone was qualitative rather than quantitative That aspect of tone which Sherrington calls "plastic" is the function of those muscle fibres innervated by the sympathetic, whereas "contractile tone" (as Langelaan has called it) is a function of the voluntary and contractile fibres innervated by medullated somatic nerves, and is, therefore, not diminished by section of the sympathetic nerves This fact is the principle that underlies the surgical operation which Hunter suggested (and of which he devised the technique) for the alleviation of those cases of spastic paraplegia due to an excess of plastic tone, but not for those in which the contractile tone alone is responsible for the spastic condition In the hands of Royle this operation has yielded results which must seem incredible to those who have not witnessed them It has placed in the hands of the surgeon a technique which is destined to relieve a considerable group of sufferers from spastic troubles not only of voluntary muscles, but also of visceral muscles, such as those of the stomach and intestine, the bladder, etc But Hunter has extended the field of his experimental investigations and has studied the nature of the proprioceptive reflexes that are concerned with the maintenance of the two varieties of tone Deiters's nucleus and the vestibulospinal tract form integral parts of the somatic arc regulating contractile tone, whereas the ponto-spinal tract (Collier and Farquhar Buzzard) is an essential part of the sympathetic proprioceptive arc regulating plastic tone His investigations have also shed a new light upon the rôle of the frontal cortex, the corpus striatum, the red nucleus, the substantia nigra, and the cerebellum as influences affecting tone

Hunter and Royle were invited to New York to deliver (October 20th) the John B Murphy Oration on their work (see *Medicine, Surgery and Gynecology*, December 1924) and they gave demonstrations in many of the great medical centres of the United States and Canada Hunter then came to England to expound the results of his work and to meet those who criticize his results By a tragic fate he was struck down in the very week when he had hoped to demonstrate to those best qualified to appreciate it the new vision of neuro muscular function created by his genius and insight He died on December 10th at University College Hospital, of enteric fever contracted before his arrival in England He was so absorbed in the mission that had brought him to England as to be unconscious of the gravity of the illness from which he was suffering The last lecture he gave was delivered on December 5th in the anatomy theatre in Cambridge the department of the master who had played so large a part in guiding his life and shaping his aims

To those who have come under the spell of his genius and learned the truth of the teaching for which he has given his life it must ever remain a duty and privilege to expound his work in the hope of convincing others of its truth and to extend its applications by experiment and clinical applica tion To his widow and the University of Sydney we extend our deepest sympathy on their irreparable loss

G I S

The funeral service was held on December 12th at St Pancras Church The large congregation included besides the widow, Sir Arthur Keith the Provost and the Secretary of University College Professors J T Wilson G Elliot Smith, J P Hill, J H Starling A J Clark C C Choyce, T R Elliott, D M S Watson and Kulchitsky Mr T P Dunhill, the High Commissioner for Australia and the Agent General for New South Wales The British Medical Association was represented by Dr Alfred Cox, Medical Secretary

The Services

No 14 STATIONARY HOSPITAL

The annual dinner of the 14th Stationary Hospital was held at the Trocadero Restaurant London on December 12th Lieut Colonel J R Harper C B E took the chair and proposed the toast of The Hospital to which Colonel J S Warrack responded It is proposed to hold the next dinner on the second Friday in December, 1925

Medical News.

DR CHARLES MAYO will be the president of the Inter State Post Graduate Assembly which is to visit this country next June, and not his brother Dr William Mayo, as originally arranged Other members of the party will be Dr Franklin H Martin, Director General of the American College of Surgeons Dr Crile, and Dr John B Deaver Writing to Mr Philip Franklin, Dr Mayo states that it will certainly be a big meeting and expresses the hope that it will do a great deal of good in promoting harmony between the medical professions of Great Britain and America and that its influence will be far reaching on the people who read and hear of it

OWING to the illness of Dr Chandler the meeting of the Tuberculosis Society on December 19th was cancelled At the next meeting, on January 16th 1925 Dr Anthony Feiling will speak on tuberculosis of the central nervous system

GUY'S HOSPITAL was founded at the sole costs and charges of Thomas Guy on January 6th 1725 In connexion with the bi centenary a solemn service in commemoration of the founder and other benefactors of the hospital will be held in the Cathedral Church of St Saviour Southwark on Tuesday January 6th, 1925, at 12 noon The Prince of Wales president of the hospital, has signified his intention to be present

THE Queen's University (Belfast) Club London, will hold a dance in the Hotel Cecil on Thursday January 15th, 1925 at 9 p m Price of tickets (to include buffet supper) members 12s 6d guests—ladies 10s 6d, men 11s 6d Application for tickets to be accompanied by remittance and addressed to the Honorary Treasurer 17 Wimpole Street, W 1

THE Fellowship of Medicine is arranging a series of general lectures at the Royal Society of Medicine the first of which will be delivered by Sir Arbuthnot Lane at 5 30 p m on January 20th, 1925, and [illegible] the treatment

Beginning on January 12th the London Temperance Hospital, in association with certain special hospitals, will hold a two weeks intensive course in the general and special depart ments of medicine and surgery A course in cardiology has been arranged from January 12th to 23rd at the National Hospital for Diseases of the Heart (attendance limited to 16) The Royal Eye Hospital, Southwark, will hold a fortnight s course in ophthalmology from January 5th to 16) ment of common diseases of the nervous system at the West End Hospital for Nervous Diseases From January 6th to 31st there will be a course in the diagnosis and treat a series of lecture demonstrations on psychological medicine at the Bethlem Royal Hospital A course in urology will be held at St Peter s Hospital from January 12th to February 7th Copies of the syllabus of these courses may be obtained from the secretary to the Fellowship of Medicine, 1, Wimpole Street, W 1

THE January class of instruction in fevers, under the Metropolitan Asylums Board, will be held on Mondays and Thursdays at the Eastern Hospital, North Eastern Hospital, and Grove Hospital, on Tuesdays and Thursdays at the North Western Hospital, on Tuesdays and Fridays at the Western Hospital and the South Western Hospital and on Wednesdays and Fridays at the Park Hospital The special course of instruction on the diagnosis and treatment of fevers will be held at the South Eastern Hospital in February and March, on Tuesdays and Fridays, at 11 a m , commencing February 3rd A three months course of lectures and demonstrations in hospital administration will be given at the North Western Hospital on Mondays, Thursdays, and alternate Saturdays beginning on January 5th Full par ticulars may be obtained from the Clerk to the Metropolitan Asylums Board, Victoria Embankment E C 4

THE annual dinner of the Old Epsomian Club was held a the Trocadero Restaurant, London, on December 11th wit the President, Mr G E Waugh, F R C S , in the chai Proposing the toast 'Floreat Epsomia' in an interesting a witty speech, Mr Waugh remarked that Epsom College w founded originally by a man of great individuality who h tul en an original line from the first in such matters as teaching of natural science, and to day it was proud of fact that its scholars developed pronounced individualities rather than passively conforming to type Individuality was also the characteristic of the teaching staff and this quality was of great value in the world to day The headmaster, Mr A C Powell responding to the toast announced some striking successes attained in the intellectual sphere during the past year The new nave of the chapel—an Old Epsomian war memorial—was now in full use The cost of erection was £12,000 of which over £10,000 had already been raised be appealed to Epsomians to make a special effort to raise the remaining sum required He hoped that it might soon be possible for more Old Epsomians to be elected to the Council The college was the school of the medical profession, and had done a great work in training medical practitioners Besides fifty boys, the sons of doctors educated year by year without charge, a sum of no less than £5 000 had been awarded last July by the school in the form of scholarships, etc The toast of "The Guests" was proposed by Mr S Maynard Smith, C B , F R C S The Right Hon Sir Hamar Green wood, Bt , K C , M P , in his reply described the medical profession as the highest instrument for good the world had ever seen it recognized no frontiers of creed, colour or race Quality rather than quantity was the most vital need for the future welfare of the British Empire, and, therefore he was particularly glad to be present that night and to extend to the college his congratulations on its past and his warmest wishes for its future During the evening the school song, *Canticum Epsomiense*, was sung enthusiastically

THE annual dinner of the British Dental Hospital (formerly British Dentists Hospital) was held at the Langham Hotel on December 6th, the President (Sir Harry Baldwin) in the chair Dr Lennane in proposing the toast of the hospital, said that it had now proved the value of its existence Mr George Thomson, in his reply, said that all the members of the staff were also members of the British Dental Association Mr E E Turner proposed the health of the guests which was replied to by Drs Fenton Duddfield, Hewat, and Caley, and Mr C E Wallis

THE Minister of Health (the Right Hon Neville Chamberlain, M P) has appointed Captain William Brass, M P , to be his parliamentary private secretary (unpaid)

THE Rockefeller Institute for Medical Research has announced the release of the drug known as tryparsamide for use in the treatment of human and animal trypano somiasis (African sleeping sickness and mal de Caderas) and selected cases of syphilis of the central nervous system This action is based on results reported from clinical investi gations which have been in progress for several years The

He cleared up many of the difficulties in the interpretation of ovarian pregnancy, in the real significance of the occurrence of Neanderthaloid characters in aboriginal Australians, and in analysing the complicated factors of spinal shock following transverse section of the spinal cord The first of these three noteworthy memoirs was published in the *Journal of Anatomy* in January, 1922 The special value of the case of primary ovarian pregnancy was due to the early period of development and the clearness of the evidence in demonstration of the fact that the ovum was fertilized as the closing coagulum was formed in the mouth of the Graafian follicle and proceeded to develop in the connective tissue in this situation, embedding itself *ab initio* outside the growing corpus luteum of pregnancy The lucidity of the account of this specimen and the interpretation of its complexities afforded the first indication to the anatomical world at large that a new John Hunter had arisen

The results of the experimental work that he carried out in collaboration with Mr N D Royle between October, 1920, and July, 1921, were not published until this year ("The symptomatology of complete transverse lesions of the spinal cord," *Australian Journal of Experimental Biology and Medical Science*, vol i, 1924, p 57) By means of an ingeniously devised series of experiments he courageously attacked a difficult problem which had taxed the skill of many of the best experimental physiologists and clinical observers of Europe and America In particular he addressed himself to the task of deciding whether or not vascular disturbances played a part in determining spinal shock He showed that the variations in the ultimate results after section of the cord cannot be wholly explained by release of function alone There may be combined with release of function (due to section of the conducting pathways), vascular changes leading to rapid degeneration, or a temporary stage of hyperexcitability of the nerve cells The experience gained in this preliminary investigation was destined to prove of far-reaching importance when, in 1922, Hunter and Royle embarked upon the still more difficult task of cutting the Gordian knot of controversy regarding the sympathetic innervation of striated muscle and the central control of muscular tone But before undertaking this work Hunter spent eighteen months in Great Britain, Europe, America, and New Zealand, getting into touch with the medical schools of the world He went first to his former master, Professor Wilson, in Cambridge, who magnanimously allowed us at University College, London, to have the privilege of Hunter's stimulating help for a whole year During that time he occupied the position of an honorary lecturer, and he taught and carried on research, gave addresses to various societies, studied clinical methods (especially neurology) in London, as well as in France, Holland, and Germany, and visited and made himself familiar with the methods of anatomical departments in most of the British and many of the Continental schools

He carried out an important research upon the oculomotor nucleus of Twisius (*Brain*, 1923), which, taken in combination with the results obtained by Brouwer, sheds important light upon the problems of human evolution He made an intensive study of the fossil remains of men, and devoted particular attention to the Piltdown and Rhodesian remains in the British Museum He devoted much time and energy to the problems involved in the reconstruction of the Piltdown skull, and showed that when the occipital region is properly reconstituted and orientated it presents a much closer analogy to the condition found in the newborn African anthropoids than does any other human skull By demonstrating that there is no disharmony between skull and jaw he has eliminated the chief factor in the controversy that had been raging for ten years before his work was done His monograph on the Piltdown problem, written in 1922, has not yet been published

During the short time he spent with Dr Arriens Kappers in Amsterdam he completed an investigation on the forebrain of apteryx (*Koninklijke Akademie van Wetenschappen te Amsterdam*, 1924), for which he was awarded the M D degree of the University of Sydney and the University medal On his way back to Australia he spent nearly three months visiting American and Canadian medical schools and not only acquired a knowledge of the scientific workers and their methods, but also rendered a great service by expounding in lectures and demonstrations the meaning of recent anatomical and neurological work in England In particular he did a great deal toward making Dr Henry Head's work on aphasia understood On his return to Australia he was made full professor of anatomy, being given the Challis Chair which Professor Wilson had formerly occupied, and he set to work to introduce the far-reaching changes incidental to the restoration of histology to the department of anatomy With the experience gained in his pilgrimage abroad he came to exercise an influence in the medical school and University, he was worshipped by the students and trusted implicitly by his colleagues

But the heavy work which these things involved did not prevent him from embarking upon a new and most formidable task—the experimental investigation of the problems of muscular tone, the solution of which had hitherto defied the leading physiologists and neurologists He attacked this intricate conundrum with confidence and courage His experimental work upon the effects of section of the spinal cord gave him technical experience and practice in observing the effects of lesions of the nervous system, his association with Professor Kulchitsky at University College had given him an exact and certain knowledge of new facts relating to the sympathetic innervation of striated muscle which were of fundamental importance in the attempt to solve his problem, and his experience of the work at Queen Square, the researches of Dr Henry Head, and Professor Stopford's work in Manchester, strengthened his assurance boldly to attack the problem He had explored the field of neurology and acquired the wider vision, he had acquired the experience of solving his own problems and of seeing other people solve theirs, he was ready to defy armchair critics and boldly to attempt the solution of the enigma of muscle tone

For several years Mr Royle had been endeavouring to devise some means of alleviating spastic paraplegia He had tried the usual surgical procedures on human patients, and by experiments on animals tried to discover some new operation, without much success He put his difficulties before Hunter on the latter's return to Australia Hunter showed him some of Kulchitsky's histological preparations, which revealed quite clearly that, contrary to the opinion expressed by Boeke and Aghdai, the sympathetic fibres to striated muscle did not go to the same muscle fibres as the medullated nerves He suggested that they should cut the sympathetic supply to an animal's limb and study the result They discovered that section of the sympathetic did not destroy tone, nor even necessarily reduce it The change in tone was qualitative rather than quantitative That aspect of tone which Sherrington calls "plastic" is the function of those muscle fibres innervated by the sympathetic, whereas "contractile tone" (as Langelaan has called it) is a function of the voluntary and contractile fibres innervated by medullated somatic nerves, and is, therefore, not diminished by section of the sympathetic nerves This fact is the principle that underlies the surgical operation which Hunter suggested (and of which he devised the technique) for the alleviation of those cases of spastic paraplegia due to an excess of plastic tone, but not for those in which the contractile tone alone is responsible for the spastic condition In the hands of Royle this operation has yielded results which must seem incredible to those who have not witnessed them It has placed in the hands of the surgeon a technique which is destined to relieve a considerable group of sufferers from spastic troubles not only of voluntary muscles, but also of visceral muscles, such as those of the stomach and intestine, the bladder, etc But Hunter has extended the field of his experimental investigations and has studied the nature of the proprioceptive reflex arcs that are concerned with the maintenance of the two varieties of tone Deiters's nucleus and the vestibulospinal tract form integral parts of the somatic arc regulating contractile tone, whereas the ponto-spinal tract (Collier and Fuquhar Buzzard) is an essential part of the sympathetic proprioceptive arc regulating plastic tone His investigations have also shed a new light upon the role of the frontal cortex, the corpus striatum, the red nucleus, the substantia nigra, and the cerebellum as influences affecting tone

Hunter and Rovle were invited to New York to deliver (October 20th) the John B Murphy Oration on their work (see *Medicine, Surgery and Gynecology*, December 1924), and they gave demonstrations in many of the great medical centres of the United States and Canada Hunter then came to England to expound the results of his work and to meet those who criticize his results By a tragic fate he was struck down in the very week when he had hoped to demonstrate to those best qualified to appreciate it the new vision of neuro muscular function created by his genius and insight He died on December 10th at University College Hospital of enteric fever contracted before his arrival in England He was so absorbed in the mission that had brought him to England as to be unconscious of the gravity of the illness from which he was suffering The last lecture he gave was delivered on December 5th in the anatomy theatre in Cambridge the department of the master who had played so large a part in guiding his life and shaping his aims

To those who have come under the spell of his genius and learned the truth of the teaching for which he has given his life it must ever remain a duty and privilege to expound his work in the hope of convincing others of its truth and to extend its applications by experiment and clinical application To his widow and the University of Sydney we extend our deepest sympathy on their irreparable loss

C F S

The funeral service was held on December 12th at St Pancras Church The large congregation included besides the widow, Sir Arthur Keith the Provost and the Secretary of University College Professors J T Wilson C Elliot Smith, J P Hill J H Starling A J Clark C C Choyce, T R Elliott D M S Watson and Kulchitsky Mr T P Dunhill, the High Commissioner for Australia and the Agent General for New South Wales The British Medical Association was represented by Dr Alfred Cox Medical Secretary

The Services

NO 14 STATIONARY HOSPITAL

THE annual dinner of the 14th Stationary Hospital was held at the Trocadero Restaurant London on December 12th Lieut Colonel J P Harper C B E took the chair and proposed the toast of The Hospital to which Colonel J S Warrack responded It was proposed to hold the next dinner on the second Friday in December 1925

Medical News.

DR CHARLES MAYO will be the president of the Inter State Post Graduate Assembly which is to visit this country next June, and not his brother Dr William Mayo as originally arranged Other members of the party will be Dr Franklin H Martin, Director General of the American College of Surgeons Dr Crile, and Dr John B Deaver Writing to Mr Philip Franklin, Dr Mayo states that it will certainly be a big meeting and expresses the hope that it will do a great deal of good in promoting harmony between the medical professions of Great Britain and America and that its influence will be far reaching on the people who read and hear of it

OWING to the illness of Dr Chandler the meeting of the Tuberculosis Society on December 19th was cancelled At the next meeting, on January 16th 1925 Dr Anthony Feiling will speak on tuberculosis of the central nervous system

GUY'S HOSPITAL was founded at the sole costs and charges of Thomas Guy on January 6th 1725 In connexion with the bicentenary a solemn service in commemoration of the founder and other benefactors of the hospital will be held in the Cathedral Church of St Saviour Southwark on Tuesday January 6th 1925, at 12 noon The Prince of Wales president of the hospital has signified his intention to be present

THE Queen's University [Belfast Club London, will hold a dance in the Hotel Cecil on Thursday January 15th 1925 at 9 p m Price of tickets (to include buffet supper) members 12s 6d members guests—ladies 10s 6d, men 11s 6d Application for tickets to be accompanied by remittance and addressed to the Honorary Treasurer 17 Wimpole Street, W 1

THE Fellowship of Medicine is arranging a series of general lectures at the Royal Society of Medicine the first of which will be delivered by Sir Arbuthnot Lane at 5 30 p m on January 20th, 1925, and deal with the treatment of fractures

Beginning on January 12th the London Temperance Hospital, in association with certain special hospitals, will hold a two weeks intensive course in the general and special departments of medicine and surgery A course in cardiology has been arranged from January 12th to 23rd at the National Hospital for Diseases of the Heart (attendance limited to 16) The Royal Eye Hospital Southwark, will hold a fortnight's course in ophthalmology from January 5th and from January 5th to 31st there will be a course in the diagnosis and treatment of common diseases of the nervous system at the West End Hospital for Nervous Diseases From January 6th to 31st Dr Porter Phillips and Dr Thomas Beaton will give a series of lecture demonstrations on psychological medicine at the Bethlem Royal Hospital A course in urology will be held at St Peter's Hospital from January 12th to February 7th Copies of the syllabus of these courses may be obtained from the secretary to the Fellowship of Medicine, 1, Wimpole Street, W 1

THE January class of instruction in fevers under the Metropolitan Asylums Board, will be held on Mondays and Thursdays at the Eastern Hospital, North Eastern Hospital, and Grove Hospital, on Tuesdays and Thursdays at the North Western Hospital, on Tuesdays and Fridays at the Western Hospital and the South Western Hospital, and on Wednesdays and Fridays at the Park Hospital The special course of instruction on the diagnosis and treatment of fevers will be held at the South Eastern Hospital in February and March, on Tuesdays and Fridays at 11 a m, commencing February 3rd A three months course of lectures and demonstrations in hospital administration will be given at the North Western Hospital on Mondays Thursdays, and alternate Saturdays beginning on January 5th Full particulars may be obtained from the Clerk to the Metropolitan Asylums Board, Victoria Embankment E C 4

THE annual dinner of the Old Epsomian Club was held at the Trocadero Restaurant, London, on December 11th with the President, Mr G E Waugh, F R C S in the chair Proposing the toast Floreat Epsomia in an interesting and witty speech, Mr Waugh remarked that Epsom College was founded originally by a man of great individuality who had taken an original line from the first in such matters as the teaching of natural science, and to day it was proud of the fact that its scholars developed pronounced individualities rather than passively conforming to type Individuality was also the characteristic of the teaching staff and this quality was of great value in the world to day The headmaster, Mr A C Powell, responding to the toast announced some striking successes attained in the intellectual sphere during the past year The new nave of the chapel—an Old Epsomian war memorial—was now in full use The cost of erection was £12 000 of which over £10 000 had already been raised he appealed to Epsomians to make a special effort to raise the remaining sum required He hoped that it might soon be possible for more Old Epsomians to be elected to the Council The college was the school of the medical profession and had done a great work in training medical practitioners Besides fifty boys, the sons of doctors educated year by year without charge, a sum of no less than £5 000 had been awarded last July by the school in the form of scholarships, etc The toast of "The Guests" was proposed by Mr S Maynard Smith, C B, F R C S The Right Hon Sir Hamar Greenwood, Bt, K C, M P, in his reply, described the medical profession as the highest instrument for good the world had ever seen It recognized no frontiers of creed colour or race Quality rather than quantity was the most vital need for the future welfare of the British Empire, and, therefore, he was particularly glad to be present that night and to extend to the college his congratulations on its past and to extend his warmest wishes for its future During the evening the school song, *Canticum Epsomiense* was sung enthusiastically

THE annual dinner of the British Dental Hospital (formerly British Dentists Hospital) was held at the Langham Hotel on December 6th, the President (Sir Harry Baldwin) in the chair Dr Lennane, in proposing the toast of the hospital, said that it had now proved the value of its existence Mr George Thomson, in his reply said that all the members of the staff were also members of the British Dental Association Mr E E Turner proposed the health of the guests which was replied to by Drs Fenton Dudfield, Hewat, and Caley, and Mr C E Wallis

THE Minister of Health (the Right Hon Neville Chamberlain, M P) has appointed Captain William Brass, M P, to be his parliamentary private secretary (unpaid)

THE Rockefeller Institute for Medical Research has announced the release of the drug known as tryparsamide for use in the treatment of human and animal trypanosomiasis (African sleeping sickness and mal de Caderas) and selected cases of syphilis of the central nervous system This action is based on results reported from clinical investigations which have been in progress for several years The

drug will be manufactured by the Powers Weightman Rosengarten Co of Philadelphia, and will become available through the regular trade channels about January 1st, 1925 In releasing the drug for the benefit of the public, the Rockefeller Institute desires it to be known that the Institute does not share in any way in profits that may be derived from the sale of the drug, and that, with the cordial co operation of the manufacturers, provision has been made for the maintenance of a schedule of prices on as low a basis as possible

THE annual report for 1923-24 of Livingstone College, Leyton, draws attention to the fact that it is now thirty two years since the College was founded to give medical instruction to candidates for the mission field During that time 810 students have entered for the full course or for part of it, of whom 540 are still actively engaged abroad During the past session the thirty five students represented no fewer than twenty three different missionary societies and eight nationalities The vacation course in July was attended by twenty four students, representing nine missionary societies, and forty seven students have attended short courses on the care of the health in the tropics The financial report shows that all expenditure during the past year has been met and the existing deficit reduced by £42 A report of the commemoration day proceedings in May was published in our columns of June 7th (p 1035)

THE fees of district medical officers under the London County Council are to remain for a further period until December 31st, 1925, at the present rate of 11s 6d a year for each person entitled to free medical attendance, the sum to include medicines and simple surgical dressings

BY an Order of Privy Council, dated December 13th, the Earl of Balfour, K G, O M, F R S, and the Right Hon William Graham, LL B, M P, have been appointed into the vacancies in the membership of the Medical Research Council caused by the retirement of the Right Hon Edward Wood, M P, and Mr A G Church, D S O, M C Lord Balfour has accepted the chairmanship of the Medical Research Council

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS *forwarded for publication are understood to be offered to the* BRITISH MEDICAL JOURNAL *alone unless the contrary be stated* Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Financial Secretary and Business Manager, 429, Strand, W C 2, on receipt of proof

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—not necessarily for publication

ALL communications with reference to advertisements as well as orders for copies of the JOURNAL should be addressed to the Financial Secretary and Business Manager, 429, Strand, London, W C 2 Attention to this request will avoid delay Communications with reference to editorial business should be addressed to the Editor, BRITISH MEDICAL JOURNAL, 429, Strand W C 2

Communications intended for the current issue should be posted so as to arrive by the first post on Monday or at latest be received not later than Tuesday morning

THE telephone number of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is Gerrard 2630 (Internal Exchange) The telegraphic addresses are

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westrand, London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc), *Articulate Westrand, London*

MEDICAL SECRETARY, *Mediocera Westrand, London*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams *Bacillus Dublin*, telephone 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams *Associate, Edinburgh*, telephone 4361, Central)

QUERIES AND ANSWERS.

INCOME TAX

Sale of a Share in Practice

"D C H" took over his former partner's share in the practice, the consideration given to be payment for four years of 20 per cent of the panel receipts less certain expenses, the payments being made quarterly How do they affect his income tax liability?

*** Our correspondent must decide on all the facts—including the negotiations preceding the sale—whether (*a*) the share in the practice was sold for an undetermined sum equal to the total of the payments to be made, or (*b*) for a four years' annuity based on the 20 per cent The latter case is a rare one, the normal transaction being essentially one of payment of a capital sum by instalments In neither case can the payments be deducted as professional expenses, but in the latter case the amount of the payments will have to be charged at the full rate of tax (without allowance for earned income), because that tax can be deducted by "D C H" when making the payments—but not afterwards

Cash Basis Retirement

"A W" refers to a reply given to his inquiry in our issue of November 15th last, and says that the local inspector refuses to accept his contention that post retirement cash receipts are not assessable on the retired practitioner

*** Our correspondent may find it useful to refer to replies in recent issues as follows to "L B C," September 13th, to "Leeds," September 20th, and to "D L," October 11th Putting the matter in a phrase, the inspector has not given due weight to the fact that the amounts of the cash receipts were taken as measures of the true income of the practice, and to the further consideration that a change of personnel in the practice does not justify a departure from the normal course of procedure When, for instance, "A W" paid tax on the average of his net receipts for 1919, 1920, and 1921, he was not paying tax on that specific income but on the income of the financial year ended April 5th, 1923 It is admitted that exceptional circumstances may from time to time justify a departure from the cash basis rule, but retirement is not, in our opinion, a fact which bears on the question Failing agreement with the inspector, "A W" might very well appeal either to the general (that is, local) commissioners, or to the special commissioners on circuit

SENSIBILITY TO HORSE SERUM

"F R C S E" writes I am in the unfortunate position of being sensitive to horse serum, usually getting a more or less severe local or general urticaria after a serum or vaccine injection I recently had an anticatarrhal injection, with the usual discomfort I intend to have some other injections later, and would welcome any suggestions for the prevention of the unpleasant after effects

LETTERS, NOTES, ETC.

AS in former years, the Automobile Association announces that its road patrols will not be on the roads on Christmas Day

KELOID VACCINATION SCARS

DR F W STANSFIELD (Public Vaccinator, Reading) writes During many years of public vaccination I have seen probably ten or a dozen cases similar to that described by Dr J Crisp in the JOURNAL of December 6th (p 1086) The condition, in my experience, never arises except when the vesicles become broken, and is probably a slight and localized "coccic" infection My cases have all been treated alike and all successfully The scars are dressed with ung resorcin co spread upon sterilized gauze, the dressings being changed every alternate day After a few days the keloid breaks down, leaving an open ulcer The treatment is continued with the same ointment, and in a week or so the ulcer heals, leaving a normal healthy vaccination scar As there are many brands of resorcin ointment on the market I may say that the one I use is made by Messrs James Woolley and Sons of Manchester

"EPHEMERIS PHARMACOLOGICA"

MESSRS OPPENHEIMER (179, Queen Victoria Street London, E C 4) apparently are not with those who would abolish Greek from the educational curriculum Even if the Greek be somewhat late, *Ephemeris Pharmacologica* is not unpleasant as a variant of "Medical Visiting List with Therapeutic Notes" The little book for 1925 which Messrs Oppenheimer offer to the medical profession is full of information, and in compiling it the authors have given heed to the appeal of Crabbe

> Oh! rather give me commentators plain
> Who with no deep research es vex the brain

The visiting list is arranged for recording the visits against any particular name for a month The therapeutic notes are brief but to the point, and appear to cover most of the drugs used in modern medicine Concise information is given on some legal matters, diet, infectious diseases, and poisons and their antidotes There are height and weight tables, a posological table tables for converting the metric system, postal information, and an almanac It is a handy book of quite small dimensions

CORRECTION

OUR report (p 1113) of the meeting of the Surgical Section of the Royal Society of Medicine held on December 3rd should have stated that the chair was taken by the President, Mr Herbert Paterson

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals, will be found at pages 36, 37, 39, and 40 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 38 and 39

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 229

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine

Sero-prophylaxis of Measles

482. S. WOLFF (*Deut. med. Woch.*, November 7th, 1924, p. 1515) records the following incidents to show how effective and lasting may be the prophylaxis of measles induced by injecting the serum of a person who has recovered from measles. In July, 1923, a 24-year-old child (B. G.) developed measles, and in the same family there was another child (H. G.), aged 1 year, who, though it left in contact with the case of measles, did not develop it. In May, 1924, a third child (G.) born in the interval and aged only 5 months, had a fairly severe attack of measles. Again the child H. G. failed to contract measles, though exposed to infection. The solution of this riddle of H. G.'s immunity was found when it came to light that H. G. had suffered from severe melæna neonatorum when only 8 days old. An injection of 30 c.cm. of the father's blood had been given, and as the father had suffered from a severe attack of measles in his youth it would seem that the immunizing bodies created in the father by the natural infection had been transmitted to the infant by parenteral administration. The author points out as a curious fact that this would seem to have lasted a considerable time. The immunity conferred by the injection of the serum of convalescents from measles is generally supposed to be very short-lived. The author suggests that observations such as those recorded point to the feasibility of preventing measles by the injection of the blood of adults who have contracted measles in childhood instead of the blood of children convalescent from measles.

453. DEYER (*Monats. f. Kinderheilk.*, November 1924, p. 134) records observations on an epidemic of measles in an institution for invalid children under 3 years of age. There were in all seventy children, of the first three who showed symptoms two died, and it was decided at once to give the others injections of the serum of a convalescent (Degwitz's method of prophylaxis). Among invalid children it was very difficult to obtain serum from uncomplicated cases, and in sufficient quantity. At first serum from a convalescent, November 1924, p. 134) the mixed serums of two children between 1 and 2 years of age. Blood was drawn from the longitudinal sinus and after separation of the clot the serum was used for injection without being further treated. It was given first to those children who were in most danger—two who had developed measles with bronchopneumonia and eight who were suffering from various forms of tuberculosis; the two former both recovered rapidly after the injection, two of the latter did not develop measles, and the others recovered without complications. Finally serum from adults was given to the remaining children, but the quantity available was only sufficient to allow each child 10 c.cm. instead of the 30 c.cm. recommended by Degwitz. Of the children under 9 months, though the chances of infection were the same in their ward as elsewhere, only one developed the disease so that 10 c.cm. of serum would appear to be almost a sufficient prophylactic dose for children of that age. For those over a year old the dose was insufficient; many developed measles but in all the course was mild and no children died. The total number of cases was fifty-five, but the only deaths were the two at the beginning.

A Fatal Case of Hydrophobia

484. F. GERARD (*Rev. Tunisienne des Sci. Méd. et Tunis. Medical*, August, 1924) records the case of a boy aged 9 who had been bitten five months previously by a dog that could not be traced and four days later had commenced a course of intensive antirabic treatment (April 28th to May 18th). Four months later, after a severe fright, he was unconscious for some minutes. From that time his mind was dulled, he lost appetite, vomited, and had febrile attacks. For three days before his admission to hospital he ate nothing and could not be induced to drink. On admission scars of bites provoked a pharyngeal spasm. On admission scars of bites on the left knee and in the left axilla were quite distinct. In spite of his hyperexcitability he was easily calmed and answered questions although in a jerky manner. His general condition was good. Although unable to drink he could swallow his saliva. A current of air or a sudden raising of the bedclothes produced a short spasmodic attack. His respiration was very irregular; several spasmodic contractions of the diaphragm were followed by apnœa for some seconds, and then a sigh. The arm movements were normal but there was paresis of the right leg, with hyperæsthesia and weak knee-jerks. The left knee-jerk was accentuated; there was a positive Babinski sign on the left side, and the Kernig sign was absent. Lumbar puncture was performed three times without relief. The cerebro-spinal fluid showed marked lymphocytosis; no organisms were found. In spite of sedatives the patient's condition grew worse; the tendon and superficial reflexes disappeared and the boy died three days later. A necropsy was refused, but the last specimen of cerebro-spinal fluid produced rabies in a guinea-pig. Gerard points out that only one other case (Konradi) has been hitherto recorded of this diagnosis being made by the inoculation test using cerebro-spinal fluid withdrawn during life.

Œsophageal Movements in Health and Disease

485. D. DANILOPOLU, D. SIMICI and C. DIMITRIU (*Journ. de Phys. et de Path. Générale*, July 1924, p. 589) have studied the movements of the human œsophagus using an air-filled ampulla communicating with a receiving tambour and water manometer recorded the pressure within the recording system. It was found that the normal stimulus is distension (bolus); this produces (1) the true reflex of deglutition, and (2) local waves of peristalsis in the œsophageal muscles. They add that œsophageal peristalsis can occur without the production of the deglutition reflex and that contrary to the classical teaching the deglutition reflex can be originated by a stimulus at any level of the œsophagus. Though the authors term the local waves reflex they do not think that they involve a nerve centre but that they are produced by the local perioesophageal nerve plexuses. The deglutition waves were found to be much larger than those of the local peristalsis. In the second paper in the same issue (p. 612) the authors report that small intravenous doses of atropine, adrenaline, and of eserine exaggerate while larger doses diminish, the contractility of the œsophagus. These chloride in any dose only diminishes the excitability. These drugs had less effect on the large waves of deglutition than on the small peristaltic waves. All regions of the tube—pure striated muscle, pure non-striated muscle, or the region where these are mixed—are equally affected. These drugs acted less intensely on the œsophagus than on the stomach. In the third paper (p. 639) the authors report four cases of tetany, organic stenosis and cardiospasm. In tetany the œsophagus showed hypermotility; this they correlate with the hypertonus characteristic of the vegetative system generally in this disease. In stenosis they find the duration of the contractions is greater than the normal, eighteen seconds instead of nine to eleven. In cardiospasm a condition of hypertonicity was observed.

Surgery

Tuberculous Spondylitis

486. A. BRUNING (*Klin. Woch.*, October 14th, 1924, p. 1916) gives a summary of the most important points in the pathology and diagnosis of tuberculous vertebral caries and an account of its treatment. In the early stage the object of treatment should be to give rest to the diseased vertebræ, and an attempt should be made to prevent spinal deformity. With intelligent children rest may be often secured by keeping the child continuously face downwards in bed; the vertebræ are thereby very slightly separated from each other. The best treatment both for children and adults is the plaster of Paris bed or shell which extends from the neck to the upper part of the thighs. Directions are given for the preparation of this apparatus in a private house. The plaster bed or shell is carefully moulded especially in the region of the neck and shoulders and the patient rests on it both by day and night. The diseased vertebræ are protected thereby from all concussion, and the pain soon disappears. After six or nine months, if the pain has ceased, the plaster of Paris bed is replaced by a plaster jacket or corset in which the patient makes the first attempt to walk. After a further six or twelve months this is changed for a cloth corset but at night the patient usually willingly returns to the old plaster of Paris bed. The beneficial effect of sunlight on tuberculous diseases has been demonstrated by Poulier and in vertebral caries sun baths or exposures of the body to the direct action of sunlight have been employed; the head being protected from the sun's rays. These exposures are increased gradually, as regards the area of the body exposed

and the duration of exposure, until the whole body is exposed to the sun's rays for several hours daily The patient should also spend much time in the open air and should sleep in it The author recommends the administration of sodium iodide, 5 to 10 grains twice daily.

487 Intracardiac Injections in Stoppage of the Heart

G NICOLICH and POTOTSCHNIG (*Rif Med*, November 3rd, 1924, p 1034) report four cases of arrest of the heart's beat during operation treated by intracardiac injection of adrenaline In the first case, a healthy young man operated on for epididymitis, though the heart had stopped beating for ten minutes, recovery took place after injecting 1 c cm of 1 in 1,000 adrenaline, the operation was finished and the patient recovered without any ill effects In the second case, an old man with malignant disease, whose heart stopped during an operation, was temporarily revived and lived for twelve hours after the injection In the two other cases (perforated gastric ulcer and tuberculous peritonitis) no effect was obtained Of all the cardio kinetics injected adrenaline was found to be the best The authors advise that the injection should be made in the third or fourth space, and as near the sternum as possible, so as to avoid injuring the pleura—the chief danger, for haemopericardium does not follow puncture They suggest that it is perhaps immaterial whether the cardiac cavity be reached or not, the adrenaline probably acts on the cardiac nerves In the second fatal case the myocardium was found to be degenerate, and in the third and fourth to be poisoned by toxins

488 Gastro-duodenal Ulcers

P DUVAL (*Bull et Mem Soc Nat de Chir*, October 25th, 1924, p 908) considers that the diversity of opinion on the correct treatment of perforated gastric and duodenal ulcers is due largely to ignorance of the real cause of the perforation As a result of investigating a number of cases he believes that the mechanism of perforation is of two kinds There is first the non infected and chronic ulcer which suddenly perforates, and, secondly, there is the type of ulcer which may be either acute or chronic, which shows evidence of inflammation, and is always microbic in origin In the first group perforation is purely mechanical, whilst in the second group it results from infection The first variety may be simply due to the giving way of a scar without evidence of an inflammatory reaction In the latter type necrosis or suppuration is present, and infective organisms, usually streptococci, are always found Some surgeons think that simple suture of the ulcer after perforation will ensure cure, and that gastro jejunostomy or excision is unnecessary Duval agrees with this as regards the first group, where the perforation is mechanical and the ulcers appear to heal satisfactorily In the infected variety he does not find it sufficient, and believes that the ulcer and the infected area surrounding it should be excised In such cases destruction by the cautery, resection, or even partial gastrectomy, give the best results, the sutures being inserted in non infected tissues He considers it possible to determine with the naked eye whether the ulcer is infected or non infected Further research is necessary, but there appears to be more oedema in infected cases The examination of the blood for leucocytosis might assist in forming an opinion

489 Syphilitic Peritonitis

S KORACH (*Deut med Woch*, October 10th, 1924, p 1402) advances various arguments in support of his hypothesis that when surgeons open the abdomen and find diffuse adhesive indurative peritonitis the condition is often syphilitic In many of these cases the appendix is very hard to find, being embedded in adhesions, but it is itself the site neither of macroscopic nor microscopic changes, and the diagnosis of chronic appendicitis is not supported by sufficient evidence To illustrate his hypothesis the author gives a detailed account of a woman, aged 39, who was admitted to hospital suffering from intermittent fever, which resisted antipyretics The Wassermann reaction was positive, and the temperature fell after a course of mercury She returned to hospital six months later with fever and rigors, complaining of weakness, insomnia, loss of appetite and weight, and persistent and diffuse abdominal pain In the right side of the abdomen a tender, slightly movable swelling, of the size of a child's fist, could be seen and felt Large doses of potassium iodide were prescribed, and the tumour rapidly became smaller The temperature fell to normal, but as the tumour had not completely disappeared, and the patient complained of attacks of abdominal pain, exploratory laparotomy was performed, and diffuse adhesive indurative peritonitis was found There was no sign of disease of the gall bladder, stomach, or appendix, the duodenum and liver also appeared to be healthy The author suggests that in an appreciable number of cases of diffuse adhesive peritonitis much can be done by antisyphilitic treatment

Therapeutics.

490 Sulfarsenol in Malaria.

L DURŒUX (*Bruxelles Medical*, November 16th, 1924, p 92) has treated more than eighty malarial patients with this drug since 1918 Six years ago he began his investigations with various derivatives of "606," and he finds that sulfarsenol is less toxic and more active than any other form, especially in the treatment of malaria His results have improved since he has given injections at shorter intervals, he now gives (*a*) a small dose once a day, (*b*) a moderate dose every second day, or (*c*) a large dose each third day He has kept most of his patients under observation during the last four years He has found it advisable in chronic cases to repeat the treatment during seasonal changes, especially in October and March, particularly in the case of patients who do not suffer from typical recurrences of malaria, but who are profoundly debilitated, with headache, anorexia, nausea, and slight fever He reports success in several severe cases of Oriental malaria In his earlier series (45 cases) the injections were given at longer intervals, there were 6 relapses among the 27 patients who reported subsequently Among the 37 patients who have received intensive treatment since 1920, 23 have been under observation for three years, and only 2 have had relapses Almost all of these patients had been treated previously with quinine, either by the mouth or intravenously, but in every case relapses had occurred Durœux believes that it is possible to prevent relapses by a series of preventive injections when the seasons change

491 Treatment of Whooping-cough by X Rays

RALPH D LEONARD (*Radiological Review*, September-October, 1924, p 10) has investigated the therapeutic action of *x* rays in this disease during the last two years He found that a single exposure to *x* rays of patients who had been having ten to fifteen paroxysms during the night reduced the attacks to three or four Routine *x* ray treatment was given during the autumn and winter of 1922 to 300 patients Careful physical examinations and blood cultures were made, and skiagrams of the chest were taken before and after treatment The ages of the majority ranged from 1 month to 6 years At first three exposures were given at intervals of forty eight hours—alternatively over the back and front of the chest Improvement resulted in at least 75 per cent of the cases, vomiting being promptly relieved A year later 20 patients were kept under constant observation *B pertussis* was isolated in 6 of them In addition to stronger dosage, treatment was limited to the roots of the lungs, both front and back Skiagrams showed that all the patients had marked enlargement of the bronchial glands, and many had peribronchial thickening About 25 per cent gave evidence of some localized infiltration or consolidation of lung tissue, but no clinical evidence of pneumonia After treatment there was a definite diminution in the size of the bronchial glands

492 Vaccine Treatment of Whooping cough

AFTER briefly summarizing the published conclusions of various writers in England, America, Italy, and elsewhere, A H MEYER, M KRISTENSEN, and E SORENSEN (*Acta Paediatrica*, October 25th, 1924, p 21) analyse the results obtained by the vaccination treatment of sporadic cases and contacts in the children's wards at the Copenhagen and other Danish hospitals, children's homes, infant asylums, private practice, and during an epidemic in the Faroe Islands The vaccine was supplied by the Danish State Serum Institute A forty eight hours old culture of the Bordet Gengou bacillus on blood agar was rubbed off with a Pasteur pipette, and an emulsion in 0 5 per cent phenol saline was prepared In 1 c cm of this emulsion there were 10,000 Bordet Gengou bacilli The vaccine was given both prophylactically and therapeutically The conclusions drawn by the authors from their analysis of this considerable mass of material are that a vaccine prepared from the whooping cough bacillus has a beneficial effect upon whooping cough when given early in the disease—that is, up to and including the first week of the convulsive stage—mainly in lessening the severity of the disease The prophylactic effect is also probably of value, although the extent of actual prevention of disease is more difficult to judge The varying action of the vaccine in some cases may be due to there being an optimum period for administration, the age of the vaccine, and the possibility of there being various types of bacillus In whooping cough the complement fixation test appears only in the third to fourth week, but in three out of six healthy children thus vaccinated the complement fixation test gave maximum readings eight days after the third injection, whereas the test was negative in the three unvaccinated children.

493. **Two New Antimony Compounds**

A LANDALL (*Amer Journ Med Sci*, November, 1924, p 723) studied the therapeutic value in cases of granuloma inguinale of two new antimony compounds—sodium antimony thio glycocollate and antimony thioglycocollamide—a triamide of antimony and thioglycocollis, administered intravenously With a maximum dosage of 0 1 gram every second day rapid cure resulted in all the cases treated, immediate relief of pain after the first injection being noticeable in some There was no evidence of antimony poisoning, and no such irritative effects occurred at the site of injection as frequently accompany the use of tartar emetic Five patients intolerant to this latter drug showed complete tolerance to these new compounds Randall adds that both can also be used intramuscularly, though the sodium antimony thioglycollate is probably the better of the two Their possible value in the treatment of syphilis is under investigation and he thinks that they should prove efficacious in other infectious conditions

494. **Calcium Chloride in Arterial Hypertension**

W L T ADDISON (*Canadian Med Assoc Journ*, November, 1924, p 1059) records observations of the blood pressure in 13 cases of arterial hypertension before and after the administration of large doses of calcium chloride In the case of 7 patients the blood pressure had been under observation for many months before the calcium chloride was given In the 6 other patients the blood pressure was only ascertained a short time before the treatment commenced In 5 cases albumin was previously present and in 4 it disappeared after the calcium chloride In 3 cases there was a low specific gravity of the urine and comparative intolerance of calcium as the kidney function improved the calcium tolerance increased The daily dosage of calcium chloride amounted to 180 grains in 8 cases, to 150 grains daily in 3 cases to 57 grains daily in 1 case, and to 75 grains daily in 1 case In all cases the administration of the calcium chloride was followed by a diminution of the blood pressure systolic and diastolic, and usually this diminution was marked

Ophthalmology

495. **Standard Backgrounds for Testing Colour Vision**

C L FEPREF and GERTRUDE RAND (*Amer Journ Ophthalmol* November, 1924, p 843) point out the importance of considering the degree of brightness of the surrounding background when making accurate investigations of the fields of vision for colour They find that the chromatic excitation is inhibited by the achromatic and that this is more marked in the peripheral field than in the central field Broadly speaking, when the background is black the fields for the lighter colours, such as green are smaller (contracted) than when the background is white The reverse is the case for the darker colours such as red To obtain uniform results they advise that a grey background should be used of the same brightness as the colour of the test object

496. **Cataract in Dystrophia Myotonica**

W J ADIE (*Brit Journ Ophthalmol*, November, 1924 p 497) draws attention to the prominence of cataract as a feature in dystrophia myotonica The actual form of the cataract seen in these cases does not appear to be very characteristic or to differ much from early senile cataract In some cases a star shaped figure of opacity in the posterior cortex of the lens was reported as being the earliest change The importance of cataract as a symptom lay rather in the familial aspect since many patients with the disease fully developed were found to have relations otherwise in good health who had presenile cataract Presenile cataract was often found in the generation preceding the one in which the disease was fully developed

497. **Progress of Senile Cataract under Hygienic Care**

E JACKSON (*Amer Journ Ophthalmol* October 1924 p 775) bases his paper upon the examination of the notes of 593 cases of patients who showed senile lenticular changes His statistics show that quite a fair proportion of the cases retained useful vision, and that in a few cases vision actually improved He points out how impossible it is to forecast the rate of development of the cataract and that therefore it is impossible to estimate the value of the many so-called medical treatments of cataract Lenticular opacities certainly clear up spontaneously on occasion With regard to the hygienic care of these cases he suggests (1) Avoidance of eye strain by proper change of glasses whenever required, good illumination, and reasonable limitation of close eyework (2) Preservation of good general health and the taking of sufficient water in the daily diet (3) Proper treatment of ocular diseases, especially those of the uveal tract, which may be associated with the lenticular opacities

Obstetrics and Gynaecology.

498. **Toxaemias of Pregnancy**

R C CHENEY (*Journ Amer Med Assoc*, November 1st, 1924, p 1383), in discussing the toxaemias of pregnancy from the ophthalmological standpoint, remarks that while fundus changes are usually only found in the graver cases they sometimes commence quite early and may afford valuable guidance in connexion with etiology, prognosis, and the advisability of allowing the pregnancy to continue Routine examination of the fundus in carefully grouped cases should give interesting information as to whether certain changes are characteristic of certain types of toxaemia Though occurring usually in the later three months of pregnancy, fundus changes have been reported as early as the third month and recurrences in succeeding pregnancies are rare Cheney thinks that pregnancy should be terminated when a retinitis develops before the last fortnight or so These fundus changes in acute toxaemia of pregnancy may range from a few retinal haemorrhages to the classical picture of albuminuric retinitis Separation of the retina may occur, the retinitis being an acute toxic condition due to retinal ischaemia rather than to vascular conditions whereas in chronic nephritis the retinitis shows more vascular changes such as narrowing of vessels increased light streak, and tortuosity Though theoretically this should afford a means of distinguishing between the two conditions Cheney thinks that this is practically impossible in the majority of cases where a pre existing nephritis was not of sufficient severity to cause vascular changes and so the sudden flaring up of the nephritis due to the extra strain of pregnancy shows more the acute toxic type of fundus Statistics indicate however that when retinitis is present the chances are four to one that the patient has nephritis

499. **Inflammatory Carcinoma of the Breast.**

B J LEE and N F TANNENBAUM (*Surg, Gynecol and Obstet*, November, 1924 p 580) describe 28 cases of inflammatory carcinoma which is held to be a distinct clinical phase of carcinoma of the breast, of any histo pathological type apparently identical with the lactation cancer, acute medullary or encephaloid carcinoma and acute bravny cancer of other writers It represents 1 3 per cent of mammary carcinomata, and frequently takes a fulminating course The authors have not observed it in pregnancy or the puerperium Ten of the patients were aged 39 or less, the average age for the whole group being 44 6 in fourteen there had been no lactation and all had pendulous breasts In the early stages diffuse enlargement without defined tumour formation was common The inflammatory reddening and brawniness of the overlying skin may extend far beyond the normal limits of the mammary gland Glandular involvement including supraclavicular adenopathy, was well marked and early in the late stages the nipple was retracted and sometimes oedematous As a rule, there was little pyrexia The authors add that the condition has been diagnosed erroneously as mammary abscess, erysipelas or radiation erythema but they think the inflammatory appearances are characteristic Microscopically the most striking change was a wide invasion of the dermal lymphatics by carcinoma They consider that the prognosis is extremely grave cases treated surgically do badly and at present radiation treatment is said to offer the only hope of palliation

500. **Double Uterus**

M GUILLEMINET and L MICHON (*Gynecol et Obstet*, 1924, v 3 p 145) summarize 48 cases of double uterus recorded in the literature antecedent to 1912 and give full reports of ten hitherto unpublished cases They emphasize the difficulty of exact diagnosis even at operation and its great importance Recognition of duplicity of the genital organs, they point out may enable conservative measures to be applied successfully The authors add that anatomical study has shown that the uterine arteries remain normal both in number and in course so that the inner border of the hemi uterus is avascular In a large number of cases they found that the pelvic peritoneum showed a well marked vesico rectal serous septum which might even extend to the pelvic colon the detection of this at an operation should lead to suspicion that the uterus may exhibit congenital abnormality The abnormality most commonly detected by clinical examination, which must include careful inspection as well as palpation was double vagina, the vaginal septum may be small and to be detected only at the superior extremity The authors point out that duplicity of the uterus is most commonly recognized after the occurrence of haematometra in one uterus, utero-adnexal infection tumour formation in a uterus or one of the adnexas or pregnancy—a frequent event in spite of the malformation Of these complications,

it is only in haematometra or pregnancy that a preoperative diagnosis is sometimes possible, if in the former case the collection of blood is unilateral, the persistence of menstrual discharges from the other side is deceptive In 19 cases mentioned by the authors in which conservative treatment of the double uterus was practised, menstruation continued, and eleven of the patients had one or more subsequent pregnancies terminated naturally or by Caesarean section

501 Treatment of Bartholinitis

H SIEBER (*Zentralbl f Gynak*, September 27th, 1924, p 2126) states that in his experience infection of one or both Bartholin glands occurs in three out of four of all cases of female gonorrhoea He criticizes the usual methods of treatment, pointing out that injections of protargol, etc, damage the epithelium, that extirpation of the gland abolishes the secretion, and that Bier's congestion and vaccine therapy are not always successful He suggests *x* rays, and describes in detail a case in which such treatment was successful Several applications were made until the secretion became bacteriologically negative No recurrence took place

Pathology.

502 Fusiform Bacilli and Spirochaetes in Pulmonary Infections

I PILOT and D J DAVIS (*Arch Intern Med*, September, 1924, p 313) present as a clinical entity a group of obscure pulmonary infections, characterized by abscess formation and gangrene In the sputum and tissues were found, by anaerobic culture, fusiform bacilli and actively motile Gram negative spirochaetes, resembling in morphology *Spirochaeta vincenti*, *macrodentium*, and *microdentium* Associated with these *Streptococcus viridans* was often present, and *Streptococcus haemolyticus* occasionally, but most constantly in the fatal cases These organisms are normally present about the tonsils and teeth, and their mode of infection is readily understood where aspiration is a factor After general anaesthesia, tonsillectomy, and perforating lesions, the secretions of the mouth rapidly give rise to pathological changes in the lungs The lesions due to these organisms are of a great variety, depending to a large extent on the resistance of the patient and the behaviour of the pathological process In all the tendency to necrosis and the production of a foul smelling lesion are the striking characteristics The simplest lesion occurs in the form of a putrid bronchitis A more commonly seen lesion is that of a bronchopneumonia consolidation in any lobe, with formation of a single abscess cavity Of great interest is the diffuse form of gangrene, which represents the action of the anaerobes at their highest pathogenic power The blood vessels in the more extensive processes are filled with thrombi which may be rich in bacteria clumps made up of fusiform bacilli, spirochaetes, and cocci, such thrombi are probably the source of metastatic lesions in the brain Acute and chronic forms of the infection occur Both abscess and gangrene may develop rapidly, cough, pyrexia, and foul smelling expectoration with the causal organisms are characteristic Abscesses may be simple or multiple, and recovery is frequent Acute gangrene ends fatally in two or more weeks In bronchiectasis the symptoms may extend over a period of many years In treatment neo arsphenamin has given encouraging results in doses of 0 3 to 0 9 gram, administered once a week, the most favourable results are obtained in early cases Surgical measures may be necessary The prevention of these pulmonary infections lies in the proper hygiene of the mouth

503 The Haemoclasic Crisis and Hepatic Function

P S COSTA (*Pensiero medico*, August 10th and 20th, 1924) states that under the name of "haemoclasic crisis" Widal has described a number of haematological and vascular reactions, of which the most important are leucopenia and a fall of blood pressure, which occur after passage into the blood of certain heterogeneous substances As the result of his own observations Costa comes to the following conclusions (1) It is rare to find all the elements of the haemoclasic crisis present at the same time, but they may appear independently of one another (2) The test cannot be regarded as positive merely because there is a post digestive leucopenia or a fall of blood pressure or any other isolated phenomenon, because these symptoms may be a consequence of shock (3) A variety of factors may give rise to phenomena indistinguishable from the haemoclasic crisis (4) Some of the phenomena characteristic of the haemoclasic crisis appear in subjects whose liver is undoubtedly normal, nor can this circumstance be explained by the hypothesis of a latent hepatic disorder, because the phenomena are seen not only after ingestion of sugar but also after swallowing plain water, in which case it is impossible to speak of colloidoclasic phenomena (5) In subjects in whom there is obvious derangement of the hepatic function the test often gives negative results, and although Widal tries to explain this by the contention that there is still a part of the hepatic parenchyma which takes on a vicarious function, this hypothesis is in flagrant contradiction with the preceding view, since it is difficult to understand how the same test can indicate a latent hepatic disorder (6) Sometimes, especially in cases where only one or two components of the test are present, the test, if repeated after an interval of only one day, yields a different result, although the state of the liver according to clinical and laboratory data remains the same (7) The test is based on the normal processes of digestion and absorption, and since it is often impossible to express a definite opinion as to the condition of the gastro intestinal canal the test loses much of its value (8) The results obtained in children should be regarded with caution, since digestive leucopenia is the rule at this age, even after small quantities of milk The same applies to pregnant women

504 Action of Papaverine on the Human Stomach

D DANIELOPOLU, D SIMICI, and C DIMITRIU (*Arch Internat Pharmacodyn et de Therap*, vol xxix, 1924, p 471) quote the statement in the textbooks that papaverine paralyses unstriped muscle Various observers have found inhibition of muscular contraction in the bronchi, uterus, etc La Fevre de Arric reported that the contractions of the stomach in dogs were weakened by papaverine, passage of food through the small intestine was also retarded, but this was not associated with intestinal paralysis The intestinal lumen was diminished and occasionally violent but ineffectual contractions were seen According to this investigator the intestinal action of papaverine is similar to that of morphine Hitherto all observations of its action on the human stomach have been clinical and radiological, the three authors, regarding these methods as unsatisfactory, have employed the method of moderate inflation of the stomach by means of a rubber bag connected with a lever and a recording cylinder Moderate distension is most important since over distension causes tetanic contractions followed by paralysis In every experiment papaverine (1 to 3 cg) was injected intravenously, the subjects being healthy young adults The authors found that papaverine acting on the human stomach produced hypermotility followed by paralysis They add that the effects of papaverine are produced more rapidly when the gastric motility is increased They consider that their researches indicate that the intravenous injection of papaverine in a certain dose excites gastric contractions, and that that is its only primary effect The phase of paralysis is apparently the inevitable result of the phase of stimulation, this is analogous to the effects of stimulation of the vagus Some time after vagal stimulation has ceased the stomach contracts more and more strongly and finally enters the stage of tetanic contraction Papaverine increases the excitability of the gastric muscle producing the first phase of increased contraction and "semitetanus" If papaverine be injected during the phase of paralysis it produces no effect, nor has it any effect if injected during paralysis produced by vagal compression

505 Antirachitic Action of Light

A F HESS (*Amer Journ Dis of Children*, October, 1924, p 517) reports the results of experiments devised to ascertain whether the treatment of inert substances with the rays of the mercury vapour lamp could endow them with antirachitic properties He found that cotton seed oil, when exposed for an hour to these rays at a distance of one foot, had acquired antirachitic potency The irradiated oil was given as food to young rats in the amounts of 0 1 and 0 25 c cm daily, the control animals receiving non irradiated oil, all the animals were fed on a standard rickets producing dietary Linseed oil, tried as an alternative to cotton seed oil, was found equally suitable, but mineral oil after irradiation developed no antirachitic properties Such properties were also absent from fluids, including linseed oil, containing radium, hydrogen peroxide, and ozonated water, none of which had any protective potency for rickets The irradiated oils with antirachitic properties were found to be unaltered as regards their content of unsaturated fatty acid, although the total acidity had somewhat increased The colour was slightly bleached and a rather fishy odour was acquired, resembling that of cod liver oil The author is at present studying the question whether the antirachitic potency of such substances as cod liver oil can be improved by treatment with ultra violet rays

A fine product from the celebrated laboratories of E. SCHERING—*a guarantee of purity and reliability*

ATOPHAN

TRADE MARK

Immediately soothes the pain and rapidly alleviates Acute and Chronic Rheumatism, Gout, Ischias, Neuralgia, Lumbago, Iritis, Pleuritis, etc

The immediate use of Atophan for Acute Articular Rheumatism prevents cardiac complications and other ill-effects associated with salicylic therapy

Supplied also for injection in the form of

ATOPHANYL.

EYESIGHT AND HEALTH

It is a proved fact that undue eye-strain, consequent upon inadequate or misapplied illumination, natural or artificial, not only weakens the eyesight itself but causes fatigue and generally impairs the health. The science of illumination is therefore a question not only for experts to study, but for employers to apply in workshops, factories, and offices, for local authorities to apply in schools, and for every single person to apply in his own home. The evils of bad and the benefits of good illumination are clearly and concisely dealt with in a paper on *Gas Lighting, Eyesight and Health*, which contains convincing pronouncements by independent authorities. A copy of this illustrated publication will be posted free to any reader who writes to the Secretary at the address below.

The B.C.G.A. representing the British Gas Industry is at the service of the public without charge for advice and help on any subject large or small connected with the economical and efficient use of gas in home, office or factory.

A letter to the Secretary of this Association will receive prompt and careful attention.

EPSOM COLLEGE

Established in 1855 as a Public School with a Royal Medical Foundation

Patron HIS MOST GRACIOUS MAJESTY THE KING
President THE RIGHT HON. THE EARL OF ROSEBERY, K.G., K.T.
Treasurer HERBERT S. PEMBLEBURY, Esq., M.A., F.R.C.S.
Chairman of the Council RAYMOND CRAWFURD, Esq., M.D., F.R.C.P.
Vice Chairman of the Council F. DE HAVILLAND HALL, Esq., M.D., F.R.C.P.
Head Master of the School ARNOLD C. POWELL, Esq., M.A.

EPSOM COLLEGE is a mile from Epsom Town, in Surrey, in a healthy situation at a considerable elevation and on the edge of the Downs. It can accommodate about 300 resident pupils. 80 of whom from 8 to 14 years of age are in the Lower or Preparatory School, which is a distinct building within the College grounds.

The College contains a valuable Library and Museum, three Laboratories—Chemical, Physical, and Biological, a Lecture Theatre, a Carpenter's Workshop, an Armoury, a Gymnasium, a Swimming Bath, and extensive playing fields covering over 20 acres for the Upper and Middle Schools, and over 6 acres for the Lower School.

Within the College grounds but detached from the main building are a Chapel, a Sanatorium with about 40 beds and a well built and suitably fitted hut to serve as an extension of Infirmary accommodation for nurses and Isolation in the event of epidemic disease.

For boys who have matriculated at the University of London, and who desire to enter the Medical Profession the First Medical Examination of that University is conducted at Epsom College, and they are spared the trouble of going to London for the purpose.

The General Council of Medical Education and Registration of the United Kingdom has included Epsom College in the list of Recognised Institutions approved of by that Council as places at which medical study may be commenced and the College has been recognised as a School of Science by the Royal Colleges of Physicians and of Surgeons for the purpose of their Conjoint Diplomas.

Boys are also prepared for the Army, Navy, Civil Service, the Universities, and for mercantile careers.

Six Medical Scholarships, differing in value, are awarded annually at the Hospital Schools in London, and 27 leaving Scholarships, ranging in value from £20 to £100, are awarded under varying conditions, some of them annually but most of them tenable for several years. Besides these there are four Entrance Salomons Scholarships of £50 a year each and 'Hugh Nardon' Scholarships of £21, Lower School Scholarships of £15, and Junior Scholarships of 50 guineas are awarded annually.

School Lists, giving full information as to Scholarships &c., with prospectuses and forms of application, may be obtained on application to the Bursar, at the College, Epsom, Surrey.

ANNUAL FEES.—Sons of Medical Men, £120. Those who are not the sons of Medical Men, £140. Day Scholars, £45.

SPECIAL FEES.—Fees are charged for the First Medical Examination Class and for other special subjects, as in other Schools.

WAR MEMORIAL THE CHAPEL

The Old Epsomian Club instituted a War Memorial Fund for the purpose of enabling the Nave of the Chapel to be rebuilt in harmony with the new Chancel, and of placing in it a suitable monument bearing the names of old Epsomians and Epsom Masters who sacrificed their lives in the war.

The work of rebuilding the Chapel was commenced in July, 1923, and the total cost will be about £11,500. As a further sum of about £2,500 is required to complete the work, the Council earnestly appeal to Old Epsomians and other friends of the College for further contributions. The War Memorial Fund is still open, and Cheques should be drawn in favour of the Epsom College War Memorial Fund, and sent to Mr. S. Maynard Smith, of 49, Wimpole Street, W.1.

Donors to this Fund will receive the same voting privileges as those given to contributors to the Royal Medical Foundation of the College.

ROYAL MEDICAL FOUNDATION

FIFTY FOUNDATION SCHOLARS receive an education of the highest class in Epsom College and are boarded, clothed and maintained at the expense of the College. They have therefore, only a few voluntary expenses. They must be elected after approval by the Council from among the sons of necessitous Medical Men who have been Registered Medical Practitioners for five years.

FIFTY ORDINARY PENSIONERS who must be legally qualified Medical Men registered for five years, or the Widows of such receive £30 a year. They must be not less than 60 years of age at the time of their application for admission as candidates and their yearly income independent of any allowance from the College must not exceed £100.

The Ordinary Pensioners and the Foundation Scholars are elected by the Governors, voting by ballot and having votes in proportion to the amount of their contributions. There is one election in the year, namely in June. Forms of application can be obtained from the Secretary at the Office of the College, 49, Bedford Square, W.C.1.

The Ordinary Pupils the majority of whom are sons of Medical Men pay fees which cover the entire cost of their board and education.

The cost of maintaining the Royal Medical Foundation has to be defrayed mainly out of subscriptions and donations the income from which fluctuates materially. It would be lamentable if it should become impossible to maintain Fifty Pensioners and Fifty Foundation Scholars as at present but a reduction in the number will be inevitable unless an income of about £6,000 can be obtained by annual contributions.

The Council therefore appeal to the profession and to the public not to allow the Royal Medical Foundation attached to the College to languish. This Foundation is entitled to support in the first place by Medical Men and afterwards by all those who are sensible of their obligations to the Medical Profession.

Donors of 10 guineas, and collectors of 20 guineas, are Life Governors of the College, subscribers of one guinea annually are Governors during the continuance of their subscriptions. Contributions of a less amount than one guinea are welcome.

Any information with regard to the details of the College will be gladly communicated to anyone addressing inquiries to the HEAD MASTER, respecting educational questions, to the BURSAR at the College, Epsom, regarding business questions, or to the SECRETARY, at the office of the College where subscriptions and donations will be thankfully received.

J. BERNARD LAMB, Secretary.

Office, 49, Bedford Square, W.C.1.

INDIAN MEDICAL SERVICE.

SPECIAL RECRUITMENT, 1924.

For not more than 13 European officers to be appointed in the immediate future special terms are offered, including gratuities of £1 000 after five years service together with free return passages for those who so long a desire to remain in the Service Otherwise the terms will be as detailed below

APPOINTMENT

The Secretary of State for India announces that these vacancies in the Indian Medical Service will be filled by direct appointment

Candidates must be under 32 years of age at the time of application and must possess qualifications registrable in Great Britain and Ireland under the Medical Acts *now in force*

CONDITIONS OF SERVICE

Up to the present time I M S officers have been employed both in the civil and military Departments of Government and have been interchangeable between the two The practice as regards employment in the civil and military side of the Service has been as follows —

At the beginning of his career an officer was employed on the military side which has medical charge of the Indian Army If he remained in military employ he held a post on the staff of a station hospital or a specialist post or a post on the administrative staff of the Army promotion being on a time scale up to the rank of Lieutenant Colonel and by selection to the ranks of Colonel and Major General He could however if he chose apply after 2 years Indian military service to be registered as a candidate for transfer to the civil side from which appointments are made to civil surgeoncies established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes and to the specialist services (for example public health and bacteriological and research departments and the professorships at the medical schools) Such transfers normally took place after about 7 years service in military employment

The Lee Commission has however recommended certain changes in the organization of the Medical Services in India and in view of their recommendations only military employment can be guaranteed to officers entering the Indian Medical Service at the present time It is however guaranteed that they will be eligible for civil employment under such conditions of service as may be made applicable to officers in future appointed to the military medical service as the result of decisions taken on the Lee Commission report

PAY

The rates of pay for European officers in the Service are as follows —

	Per mensem (consolidated)
Lieutenants	650
Captains	800 for 3 years 950 3 years 1 050 3 years or until promotion to the rank of Major
Majors	1 200 for 3 years 1 350 3 years 1 500 , 2 years or until promotion to Lieut Colonel
Lieut Colonels	1 750 for 3 years 1 850 in 24th and 25th years of service 1 950 from 26th year of service 2 100 when selected for increased pay
Colonels Major Generals	2 200 to 2 500 } according to the appointment held 2 750 to 3 500 }

The above rates include an overseas allowance of Rs 150 *per mensem* for the first six years, Rs 200 *per mensem* for the next six years, and thereafter Rs 250 *per mensem* which will be admissible to officers of non Indian domicile only

It may be pointed out to intending candidates that the initial rate of pay for the Indian Medical Service and all Government Departments are based on the assumption that the majority of newly appointed officers will be bachelors It is also the case that an officer when junior is liable to more frequent changes of station than later on in his service and he may therefore be put to considerable expense for transfers if he has a family Officers, therefore who join the Service married may have considerable difficulty in living within their pay during the first few years of their service

Extras —In addition to the above rates, officers in military employment, when in command or second in command of the larger station hospitals, receive special allowances On the civil side there are public health bacteriological, research, and professorial appointments carrying special enhanced rates Special rates of pay are attached to the administrative appointments open to officers in both branches of the Service

PRIVATE PRACTICE

Executive medical officers in both civil and military employment may attend persons unconnected with Government service provided their duty admits of it Candidates are, however *informed that while serving on the military side the opportunities* for private practice are not great

WAR SERVICE

Service during the war as a medical or combatant officer or in a position usually filled by an officer counts towards promotion and pension so long as the rights of officers who have entered by competition are not interfered with

PENSIONS

The rates of pensions are as follows —

Service	Rate per annum	Service	Rate per annum
After 17 years	£400	After 23 years	£520
18	£430	24	£560
19	£460	25	£700
20	£500	26	£750
21	£540	27	£800
22	£580		

The above rates are subject to revision upwards or downwards to an extent not exceeding 20 per cent in all from the 1st July, 1924 and every three years thereafter The revision due this year will take the form of a reduction not exceeding 5½ per cent but the exact amount has not yet been decided

There are additional pensions ranging from £125 to £350 per annum for officers who have held high administrative appointments as Colonels or Major Generals These pensions are not subject to the reduction mentioned above

PASSAGES

Officers on appointment are when possible provided with passage to India by transport When such accommodation is not available passage at the public expense is provided by private steamer or passage allowance is granted if preferred The wives and families of officers who are married prior to the date of the officer's embarkation on first appointment to the Indian Medical Service will also be provided with passage to India at the public expense under the same conditions as those applicable to the officers themselves

During the course of their service officers of the Indian Medical Service in military employ are entitled to passage from India to the United Kingdom and back whenever they are granted sick leave by a medical board in India

If married their wives and families will also be granted passages to and from India to accompany them Further when the families themselves are upon the recommendation of a medical board in India invalided home for the preservation of life they may be granted free passage subject to the proviso that in neither case will families be provided with free passage *if during the preceding five years they have received free* passages in any circumstances

INCREASED CADRE

Formerly the allowance for furlough was 20 per cent This has now been increased to 25 per cent Previously there was no allowance for study leave now the cadre has been increased 2½ per cent for study leave, making a total of 27½ per cent Whilst on study leave there are special allowances

OPPORTUNITIES FOR RESEARCH

There is a Special School of Tropical Medicine in Calcutta, and Pasteur Institutes at Kasauli and Guindy

Further particulars can be obtained on application to the Secretary Military Department India Office Whitehall, London S W 1 Letters should be marked Recruitment for I M S

Malayan Medical Service.

(STRAITS SETTLEMENTS
FEDERATED MALAY STATES,
AND
UNFEDERATED MALAY STATES)

THERE are vacancies for Medical and Health Officers in the Malayan Medical Service on the time scale below the senior posts Candidates, who should not be over 35 years of age, should apply to the Private Secretary (Appointments), the Colonial Office, Downing Street, London, S W 1

2 Below the senior posts are appointments on a time scale salary which over 16 years rises from an initial salary of $5,280 (£616) a year to $9 600 (£1,120) a year by annual increments of $240 (£28) a year for the first four years and thereafter of $300 (£35) a year Selected candidates will be appointed at the initial salary of the scale, viz , $5,280 a year

3 On all salaries a temporary allowance is at present paid of 10% to unmarried and 20% to married officers Salaries are paid monthly

4 Senior posts and salaries are at present as follows —

Principal Civil Medical Officer, Straits Settlements, and Principal Medical Officer, Federated Malay States, $14,400 (£1,680) per annum

Director Government Laboratories, Federated Malay States, $13,200—$13,800 (£1,540—£1,610) per annum

Principal of the College of Medicine, Straits Settlements (Class A), $13,200 (£1,540) per annum

Chief Health Officer, Singapore (Class A), Senior Surgeon, Singapore (Class A) Senior Health Officer, Federated Malay States Chief Medical Officer, Singapore (Class A), Senior Medical Officer, Perak Senior Medical Officer, Selangor Senior Surgeon, Kedah, Chief Medical Officer, Penang (Class A) Principal Medical Officer, Johore, $12,600 (£1,470) per annum

Ophthalmologist, Federated Malay States, Chief Surgeon, Federated Malay States, $12,000 (£1,400) per annum

Pathologist Singapore, Superintendent, Central Mental Hospital, Federated Malay States, Bacteriologist, Federated Malay States, Professor of Surgery, College of Medicine, Senior Medical Officer, Negri Sembilan Senior Medical Officer Pahang, $10,200—$12 000 (£1,190—£1 400) per annum

Professor of Physiology, College of Medicine Professor of Midwifery, College of Medicine, Professor of Anatomy College of Medicine Chief Medical Officer, Malacca, $10,200—$12 000 (£1,190—£1 400) per annum

Pathologist, Penang, $8,400—$9,600 (£980—£1,120) per annum

Malaria Research Officer Federated Malay States, $6,600—$9,600 (£770—£1,120) per annum

5 The currency of the Straits Settlements and the Malay States is based on the Straits Settlements dollar All salaries are fixed in dollars and are so paid while officers are on service in the Colony For purposes of paying salary when on leave or pension after retirement, dollars are converted into sterling at the Government rate of exchange, which is at present 2s 4d to the dollar No change has taken place in this rate for the past 18 years and no alteration is contemplated so far as can be foreseen at present

6 After three years satisfactory service an officer is usually placed on the permanent establishment

7 In the Federated Malay States on quarters provided by the Government and on the furniture provided, a rent ranging between $26 50 (£3 1s 10d) and $65 (£7 11s 8d) *a month* and depending on the salary and the class of the quarters is charged while in the Straits Settlements the rent on all quarters is 6% of the officer's salary Quarters are usually available

8 Eight months leave on full pay with at present a free return passage is granted after every four years service, and casual leave may be taken locally in addition Leave on full pay counts for pension

9 Free passages are provided on appointment Half salary only is paid on the voyage out

10 Information and advice generally regarding mode of life, climate cost of living, outfit, and other particulars should be sought from Sir E L Brockman, K C M G , The Malay States Information Agency, 88, Cannon Street, London, E C 4

Valentine's Meat-Juice

In the Gastric Form of Influenza and its Debility, in Typhoid and Acute Pneumonia, in the Exhaustion of Phthisis and Pulmonary Diseases, Valentine's Meat-Juice Sustains and Strengthens

When Other Food Fails

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

Trufood is standardised as regards each constituent and contains an unvarying 26 % of butter fat.

There is a mass of clinical evidence to prove that Trufood is a satisfactory substitute for human milk.

Trufood is a scientific alternative for human milk

Whatever claims are made for other infants foods none when subjected to the test of analysis can show a closer approximation to breast milk than Humanised Trufood The latter as the following figures clearly prove makes available for the first time a product which whilst containing nothing but the solids of milk is practically identical in composition with human milk when reconstituted with water

	Breast Milk	*Cow's Milk*	*Humanised Trufood*
Lactose	6.5	4.7	6.45
Fat	3.3	3.5	3.45
Casein	0.7	3.0	0.70
Lactalbumin	0.4	0.5	0.60
Salts	0.2	0.8	0.65
Water	88.9	87.5	88.15
	100.0	100.0	100.0

Freedom from starch—No starch or products of starch conversion occur in Trufood The only carbohydrate present is milk sugar This is of importance since all authorities are agreed that starch whether free or converted is harmful in infant feeding The child fed on Trufood digests its food well shows steady growth of bone and muscle and develops sound healthy flesh and not unhealthy fat

You are invited to apply for reproduction of actual photograph (in colours) of results obtained by feeding of various milks This is but one of many proofs

Samples adequate for full clinical trial together with descriptive literature on request

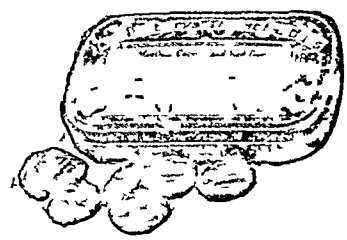
The 'Allenburys' PASTILLES

Glycerine and Black-Currant Pastilles

Delicate in flavour *Efficient in use*

They are manufactured from pure glycerine and the fresh juice of choice ripe black currants by a special process which conserves the full value and flavour of the fruit The 'Allenburys' Glycerine and Black Currant Pastilles have a demulcent and mildly astringent effect, most useful in allaying simple irritations of the throat They dissolve slowly and uniformly, and have a delicious and slightly acidulous flavour.



Supplied in metal boxes containing 2 ozs 4 ozs. 8 ozs and 1 lb respectively

The 'Allenburys' Medicated Pastilles

may be relied upon to present the accurate amounts of the active ingredients and to be thoroughly effective in use They dissolve slowly and uniformly, ensuring a thorough suffusion of the medicament over the mucous membrane 81 varieties of the 'Allenburys' Medicated Pastilles are manufactured

Descriptive Booklet and Price List sent on request to members of the Medical Profession

Packed in original tin boxes containing 3 ozs 8 ozs, and 1 lb respectively

Note on the use of Dimol

in

SURGERY

In view of the experience of a large number of observers who have found that the growth of gas-producing organisms which cause severe pain after abdominal operations may be effectively controlled by the use of Dimol, a distinguished surgeon has suggested that its free administration, both before and after the operation, would obviate the discomfort and pain which only too often follow such surgical measures

As the experience of surgeons has proved that flatulence, if not controlled, may even imperil life, the above procedure should be worthy of serious consideration

Literature and Samples may be obtained from

7 GREAT MARLBOROUGH STREET, W.1

FACTS ABOUT SMALLPOX & VACCINATION, 1924

Just Published in pamphlet form Quarto 34pp in paper cover.

A REVISED EDITION OF THE ABOVE EDITED BY

JOHN C. McVAIL, M.D., D.P.H.

The last edition of this pamphlet was published in 1905 The present publication presents, in convenient form, illustrations of the more striking groups of facts proving the value of vaccination, comments on allegations made from time to time in its disparagement, and discusses the position of smallpox and its prevention in this country at the present time

Price 6d., post free 7d

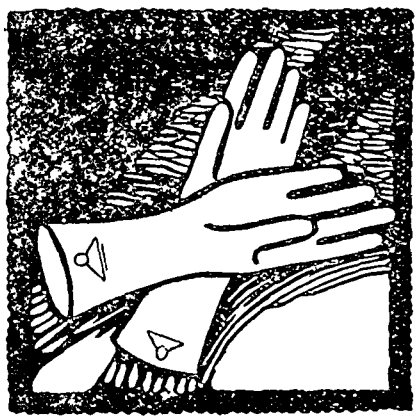
To be obtained from THE BRITISH MEDICAL ASSOCIATION,
429, Strand, London, W C.

This picture and piece of conversation are extracted from advertisements which have been appearing in the leading papers of Great Britain Their aim is to make the deaf see their infirmity in a clearer light, and realize the desirability of taking it in hand

Dilemmas of the DEAF

MARIE Why, where are you going, dear?

IMOGEN Home I can t stand it any longer



MARIE Why whatever s the matter? I m enjoying it immensely!

IMOGEN You are yes you can hear it I can hear about one word in three! I'll never come to a theatre again!

MARIE Don t be so tragic dear! Why ever did you come without an AcoustiCON? I had no idea you d been taken deaf like this since I was last with you, or I d have made you get one before we came

We are always glad to co operate with Doctors and they are always welcome in the AcoustiCON demonstration rooms whether accompanying patients or seek ing information Apart from the great number of persons who are now buying AcoustiCON Hearing Aids for the first time it is of great interest that many churches are installing the Multiple AcoustiCON with very satisfactory results

CHILDREN'S EDUCATIONAL ASSURANCE

Provide for your child's education NOW

Don't wait until the school age and then discover that you cannot afford the cost of the education which you had intended

By paying a regular annual sum for the next few years you can secure the following benefits —

(1) An annual payment to you by the Society for five years, commencing at any date chosen by yourself This enables you to meet school and college fees

(2) A single cash payment at the date chosen in lieu of the five annual payments

(3) The return of all the money which you have paid if you wish to discontinue the policy after you have made three annual payments

(4) In the event of your own death before the date which you have chosen for the commencement of the five annual payments by the Society, no further payments will be due from you to the Society The five annual payments will, however, be made to your executors when they fall due, thus providing the necessary funds for your child's education even if you died after making only one payment to the Society

Write for particulars of Scheme "B 5" to the Manager and Secretary

THE NEW FORM OF COD-LIVER OIL

Entirely free from that repellent fishy flavour and smell.

In all conditions where Cod-liver Oil is required, and where it cannot be taken owing to its repellent fishy flavour and smell, "Gadus Jelly" is strongly recommended

Perfected after long experiment by the noted Norwegian Chemist, PETER MOLLER HEYERDAHL, "Gadus" Jelly is a deliciously flavoured product about a hundred times richer in "A" vitamins than butter, containing approximately 30% Cod-liver Oil

HEYERDAHL PRODUCTS Co. (England), Ltd.,
36, Regent Street, CAMBRIDGE

FOR INTERNAL TREATMENT OF
GONORRHŒA, URETHRITIS AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT.

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years
Distilled from carefully selected Mysore Sandal Wood the oil is bland and remarkably
FREE FROM THE IRRITANT AND NAUSEATING EFFECTS
which are provoked by many preparations
There is marked absence of gastric and other disturbances diarrhœa and skin eruptions Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or intolerance

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-Urinary tract

The Capsules contain 5 drops and usually 10 to 12 are given daily in divided doses

Prepared in the Laboratoire de Pharmacologie Generale 8 Rue Vivienne Paris and sold by most Chemists and Wholesale Druggists throughout the World

UK Agents WILCOX JOZEAU & Co

Fine Pure Wool Sheets

It might be thought that a woollen sheet can only be a modified blanket and therefore not quite suitable but this is not the case

Jaeger Pure Wool Sheets are made of a fabric much lighter and smoother than the flannel which is very often worn next the skin They are in fact as smooth as linen or cotton with the advantages and comfort which wool gives

They are warmer in the winter and cooler in the summer because wool is a slow conductor To the invalid a wool sheet is of special value but anyone of good health who has also tried one never abandons it if only on account of the luxurious ease which a Jaeger Sheet gives

White Wool "Taffeta" Sheets
for Single Bed **43/6** each, for Double Bed **75/-** each

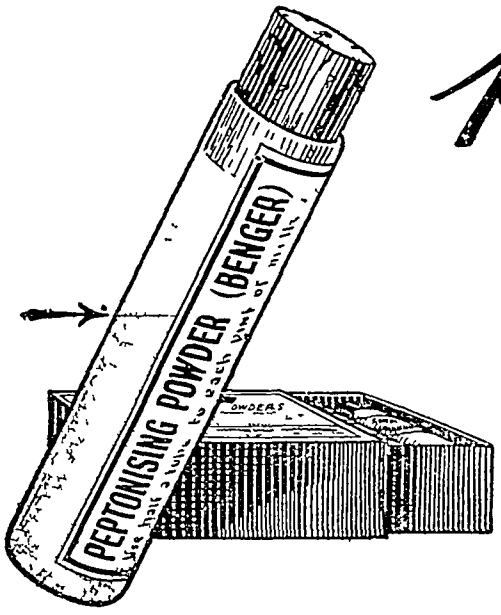
Intestinal Disinfection
No. 1.
ALIMENTARY TOXÆMIAS

PUTREFACTIVE bacteria increase in numbers in the intestine as age advances They are relatively scanty in the young child, but after middle life are usually present in considerable numbers Of the micro organisms concerned proteolytic anærobes are probably the most important

In individuals with a normal intestine and free evacuations they may do little harm but in those subject to intestinal catarrh these putrefactive bacteria become more numerous and active their products are formed in greater quantity and are more freely absorbed and the condition of alimentary toxæmia results The manifestations of this state are very protean—*e g* rheumatic conditions digestive upset neurasthenia and neuralgias increased blood pressure and its complications and many others The treatment in the first place obviously should be *intestinal disinfection* For this purpose nothing surpasses the use of KEROL CAPSULES They have solved for years the question of disinfection of the alimentary tract They definitely reduce the bacterial content of the intestine as shown by the reduction in *B coli* by 99% when the Capsules are regularly administered for a period of from 7 to 10 days



We have from time to time published several booklets containing clinical evidence as to their value and these we will gladly forward on receipt of a postcard to any member of the Medical Profession

KEROL CAPSULES

In subsequent advertisements we shall discuss and indicate the various conditions in which KEROL CAPSULES have been proved successful

Please send for literature and samples which will be sent free to any member of the Medical Profession

Half a tube!

Half a tube of Benger's Peptonising Powders is enough to peptonise a pint of milk, gruel or soup in most cases in 10 minutes Generally speaking, this is half the quantity required of other preparations whose initial cost is much higher.

BENGER'S

PEPTONISING POWDERS

are therefore most economical in use and rapid in result Professor Stirling says.

"The great value of such foods has been elucidated by Sir William Roberts, while Mr Benger has been able to prepare solutions capable of rapidly producing this result."

Prices No. 1—Box of 6, 1/-; No 2—Box of 12, 1/8.

VACCINE TREATMENT FOR TUBERCULOSIS

Detoxicated Tubercle Bacillus Vaccine is prepared from virulent strains of Tubercle Bacilli The germs are subjected to mechanical disintegration in the presence of weak alkali which acts as a solvent of the liberated bacterial protoplasm. The waxy or "fatty" portion, forming an insoluble residue, is completely separated by filtration through Berkefeld filters and is discarded, consequently this preparation is a

"DEFATTED" VACCINE

as well as a Detoxicated Vaccine

(See BRITISH MEDICAL JOURNAL, *7th July, 1923)*

A large quantity of this Vaccine is now available.

HALITOSIS

(AS DEFINED IN THE CENTURY DICTIONARY)

(Hal i to-sis) N N L

(L Halitus—Breath Osis—Offensive)

Offensive breath, whether arising from diseased or neglected conditions of the teeth, mouth or nose or caused by disorders of digestion, respiration the excessive use of tobacco, etc. may be readily overcome by the deodorizing properties of—

LISTERINE

Listerine is strictly antizymotic, it inhibits alike the acid fermentation of carbohydrates and the alkaline putrefactive processes of mixtures of meat and saliva, retained as debris about the teeth, hence, Listerine is antagonistic to the activating enzymes of fermentation so often the cause of Halitosis

The volatile antiseptic constituents of Listerine-thyme, eucalyptus, gaultheria and mentha, combined with baptisia, boric acid, rectified spirits and water have a stimulating effect upon the stomach and in proportion to the dose, an action inhibitive to fermentation of its contents, hence, Listerine is often corrective of those disorders associated with the endo development of gases and acid eructations. A large tablespoon of Listerine in a wineglass of hot water will afford immediate relief

COLLOSOL ARGENTUM

(CROOKES).

A non-toxic, non-irritating, and stainless antiseptic.

CHIEF INDICATIONS.

Dermatology Its antiseptic powers towards lower organisms without injuring delicate tissues give it obvious advantages in all skin affections

Ear, Nose, and Throat Conditions. In nasal and laryngeal inflammation and all catarrhal conditions the drug has given marked satisfaction

Ophthalmic Cases The outstanding advantages of Collosol Argentum are recognized by ophthalmic surgeons to whom its effectiveness and freedom from even slightly irritant properties makes a great appeal For prophylaxis against ophthalmia neonatorum it is already in use by some sixty County and Local Medical Officers of Health for the midwives under their control

Genito-urinary. The non-irritant properties of the drug for the highly sensitive mucous membranes of the genito-urinary passages are fully realized

Some Clinical References.

BRONZE BELL EMPLOYED IN THE RITUAL OF ANCESTOR-WORSHIP AN IMMEMORIAL AND PERSISTENT FORM OF CHINESE RELIGION —Ancestor worship was an established cult as far back as Chinese history is available The Chinese believed that their ancestors lived somewhere after death, could come to them at call, watched over the interests of the family, and could work its members good or evil Upon this belief grew up the worship of ancestors, which was the only worship for all people in early times in China Offerings were made to ancestors for the purpose of obtaining from them benefits and blessings or to conciliate them Even at the present day each family preserves in a shrine wooden tablets upon which are written the names dates, etc of its deceased members, every clan has its ancestral temple containing like tablets, before which incense is burned daily, and where twice a month ceremonial offerings of food are made All important family events are announced to the ancestors In ancient times a bell, similar to the one suspended before the banqueting hall to summon the guests, was sounded to call the shades to the repast prepared for them in the ancestral temple The inscription upon the ritual bell here reproduced contains the following —"I, Kuo Siu Lu, say Grandly distinguished was my illustrious father Hui Shu with profound reverence he maintained a surpassingly bright virtue He excelled alike in the rule of his own domain and in his liberal treatment of the strangers from afar When I Lu presumed to assume the leadership of the people and to take as my model the dignified demeanour of my illustrious father, a memorial of the event O illustrious father seated above, protect with sheltering wings us who are left here below Peaceful and glorious extend to me, Lu, abundant happiness I Lu, and my sons and grandsons for ten thousand years to come, will everlastingly prize this bell and use it in our ritual worship" Ancestor worship remains to day the chief religious practice of the Chinese The pioneers who evolved and spiritualised it were benefactors, for the filial piety it inculcates is a great moral asset of the race, despite the possibility of certain pitfalls some see in it

CHINESE INSCRIPTION OF THE NINTH CENTURY B C MAKING REFERENCE TO A MINISTEP OF EDUCATION.—The Chinese justly deserve the title of pioneers in education notwithstanding that their subjects and methods of education early became unduly formalised No nation can vie with China in the importance she attached to the subject from very early times even if the remote antiquity she claims for her educational system cannot be accepted Her great teachers—Lao zu Confucius and Mencius—actually instructed the people between 600 and 300 B C and the way must have been prepared for them during many preceding generations The claim is made that the germ of the Chinese system of education existed in the third millennium B C and that Wu Wang (1122 B C.) the first emperor of the Chou dynasty established schools divided into six classes of which the three lower were intended for boys of from eight to fifteen years. The inscription here reproduced records an emperor's visit to the temple to offer burnt sacrifices and relates that Pan Chung the Minister of Education came in at the gate and stood in the middle of the audience hall. It also mentions the presence of a historiographer who had been summoned to record the proceedings

Date c. 900—800 B C.

ESTABLISHED A.D 1715

The Ambulatory Treatment of Fractures and Diseased Joints,

By CAREL A. HOEFFTCKE

7, HARLEY STREET, LONDON, W 1

More than twenty years have elapsed since I first introduced the Ambulatory treatment for acute and chronic disease of joints, and for fractures of the long bones of the lower extremity

As is the case with many revolutionary changes in medical and surgical procedures, this treatment has met with a varied reception, but the numerous and favourable reviews of my book, in home and foreign medical papers, which have appeared, show that the principle involved in the Ambulatory treatment, namely, extension combined with movement, has found great favour with the medical profession

The difference between, and the advantage of, the Ambulatory treatment over the recumbent, must be apparent in cases of neck of femur fracture in elderly people as it obviates the danger of congestion of the lung, when the patients are enabled to assume an upright position and walk about within a week of the accident

When the patient is in the upright position, the circulation is not impaired, which therefore allows callous to form and union to be obtained more rapidly than if the patient has to lie in bed

In cases of tubercular and arthritic disease of the joints, the patients can be allowed to walk about and exercise the joints, which avoids slowing of the blood supply, and enables the usual blood current to combat the disease, and repair the articulating surfaces

The Ambulatory Extension treatment has upset the accepted opinion that nothing can be done to arrest the progress of the disease in cases of rheumatoid arthritis or even to prevent consequent deformity contractures, ankylosed joints, etc Hopeless cripples, who have been unable to walk for years, have not only obtained moveable joints, but also have been enabled to have the free use of their limbs without any evidence of the disease remaining

---

Extract from the MEDICAL PRESS AND CIRCULAR, *April 9th, 1924, pages 293—296*

RHEUMATICS

BY AN EMINENT PHYSICIAN

"GENTLEMEN—The subject you have chosen for discussion is one which, though of the greatest importance, happens to be, at the moment, very obscure and difficult

" Thus one finds as one blunders about in this swamp of 'Rheumatics' that each stone you try to step upon tilts you up and plays you false

" Lastly, there is one method upon which I would like to say a few words, though I must deal with it cautiously There are cases of severe arthritis in which the disease has become quiescent, but in which, either owing to the initial severity, or from lack of knowledge, or the character of the patient, severe contractures have resulted, one or both knees, for example, have become fixed at a right angle and the patient has been unable to walk, possibly for years These are sometimes dealt with by forcible extension and elaborate splints—a treatment associated with the name of Mr Hoefftcke

" This, however, I must say, that in three out of four cases, all of the worst type, in which I followed through the results, they were eventually remarkable The fourth case, a hip-joint affected with osteo-arthritis, was a failure, but I am not prepared to alter my mental attitude because this was a failure, for the cases I am dealing with are most difficult, and there must be failures I can only repeat that I have seen three remarkable successes When I am faced by a patient with contractures of long standing, unable to walk or earn his living, I ask myself What method other than this is open to use? "

Extract from the MEDICAL PRESS AND CIRCULAR, *May 14th, 1924, page 406*

RHEUMATICS

BY CAREL A HOEFFTCKE

" The danger of injury does no doubt exist if the wrenching is done without extension Under such conditions the joint surfaces are pressed together by strong muscular tension, and as the surfaces are usually eroded there is serious danger of injury If, however, the joint surfaces are kept separated while the manipulation takes place this danger is avoided Such separation can only be obtained satisfactorily by an extension table or extension splint Further, the suffering which the patient has to face is in a large measure due to the contact of the diseased joint surfaces and is, accordingly, greatly reduced by suitable extension Cases treated by my ambulatory extension method in arthritic or tubercular disease need not be quiescent, in fact, the earlier the extension treatment is applied the sooner a good result can be expected. . . . "

"The Lancet," *January 5th, 1924 review* —

" And it should be stated clearly that he works only with the medical profession and not as one who offers a substitute for medical services "

DEC 27, 1924]

An Address on THE TEACHING OF OBSTETRICS

DELIVERED TO THE EDINBURGH OBSTETRICAL SOCIETY BY B. P. WATSON, M.D., F.R.C.S.I. PROFESSOR OF MIDWIFERY AND DISEASES OF WOMEN, UNIVERSITY OF EDINBURGH, PRESIDENT OF THE SOCIETY

[FOLLOWING some introductory remarks, Professor Watson continued as follows:]

I propose in this address to direct your attention to what may be accomplished in the future, to inquire whether we are laying the proper foundations for advance and whether we are embodying in our teaching the advances already made in such a way as to make them available to the graduates of our medical school.

A calm review of present conditions is always helpful. Most of us are so busily engaged in the daily round of practice and teaching that little time is allowed for reflection. Things we have done in the past we are inclined to continue to do out of mere habit or because of a certain mental laziness which makes the effort of change seem too great. Tradition has its drawbacks as well as its advantages. Conservatism is to be commended when it makes us hold on to the things which are of proved value, but it must be condemned if it renders us incapable of appreciating and making full use of the new aid which emerge with time. This leads up to the questions I am going to put and to attempt to answer. Has our teaching of obstetrics and gynaecology kept pace with the advances made in these subjects in the last twenty years? Does our teaching equip the young graduate for the work he is expected to do when he leaves the medical school? Is the training of our midwives and nurses carried on in such a way as to give the maximum of benefit to the community and to themselves?

The advances made in obstetrics in the last thirty years have been mainly in two directions: in the perfecting of the technique, including a much better understanding of the indications for, and limitations of, the various operative procedures, and in the recognition of the importance of ante-natal examination and supervision. We have travelled so far along these two lines that, theoretically, we should already be seeing the results in a reduced maternal mortality throughout the country. That reduction, unfortunately, is not yet evident, and it is one of my purposes to-night to try to arrive at the reasons for this disappointing result.

I am not going to weary you with statistics. These have been cited over and over again in numerous publications and have been investigated by different commissions which have been set the task of inquiring into them. All these tables, for England and Wales for Scotland and for most other countries, tell the same tale of a maternal mortality of from 4 to 6 per 1,000 more or less constant for the past twenty or thirty years. The general death rate has been reduced by one third, the infant mortality rate has been halved since the beginning of the century, yet the maternal mortality rate is little lower than it was twenty years ago." Whilst this statement is justified by the statistics available we must not take them too literally. I think there can be no question that there has been a reduction in maternal mortality in the hands of individual practitioners and in our maternity hospitals. The individual practitioner carrying on an obstetrical practice according to modern ideals has better results than he would have had thirty years ago, that time. Notification of deaths due to puerperal causes is more complete to-day than it has ever been, so that a larger proportion of such deaths are tabulated than was formerly the case. Notwithstanding those corrections we must still regard the figures as too high. And apart from mortality, can any of us say that morbidity due to childbirth is any less in its incidence than it was? The numbers of cases awaiting admission to our gynaecological wards for operative treatment supply the answer. Why is it that in this one field of medicine there is so little to show in the way of improved results? The answer must be that, for some reason or reasons, we, as a profession, are not putting our theories into practice. This failure on our part is due to several causes. One of these, undoubtedly, is the inadequate training of our students, but whilst I shall devote most of my time to a consideration of means for improving this we must not forget that other factors play a part. A large share of the responsibility rests on the general community. It must supply the funds for the improvement of medical education, for the erection and maintenance of larger and better maternity hospitals, for the provision of ante-natal care, and for the supply of proper equipment for the conduct of labour in the houses of the poor. The economic problem is one which we must leave to our statesmen to solve. Until it is solved no great advance is possible. Meantime, it is for us to form public opinion by stating the case and suggesting remedies.

Textbooks and Systematic Lectures

Let us then, first consider the training of our students for on this depends advance in all other directions. I need say little about theoretical teaching. I am still a believer in systematic lectures. From these the student ought to obtain the foundation on which to build his clinical experience. These lectures have formed in the past a very distinctive and valuable method of teaching in our Scottish universities. To-day they still have their place, but in a modified form. Twenty or thirty years ago there were very few textbooks, and these were not always available to the student. Each subject could be more or less completely covered in one hundred lectures, and the student's notes came to constitute his textbook. Now that has all changed. Many good textbooks are available in all subjects. It is no longer possible to cover the whole or any one of the major subjects in a course of one hundred lectures. Some modification of the method is thus necessary.

If an adequate understanding of the subject is to be got, if time and energy are to be conserved for the teaching and learning of the practical and clinical sides more and more use must be made of reading for the acquisition of the groundwork by the student. The lectures therefore should not be a mere reiteration of textbook articles, but should reflect the individual experience of the lecturer. If they do not do so they fail of their purpose. They should deal with broad general principles and be freely illustrated by clinical pictures. They should be supplementary to, but not a substitute for, a textbook. Their chief object should be to give the student a proper perspective of the subject and to direct him in his reading and in his clinical work. In midwifery these objects can be easily attained in fifty lectures, while from fifteen to twenty ought to suffice for gynaecology. During this course the student ought to have access to the museum and practical room of the department where he can acquire a first hand knowledge of pathology and make use of models, manikins and instruments. This is the scheme which we are now following in the University of Edinburgh.

Clinical Instruction

After such an introduction the student is in a position to acquire clinical knowledge. Hitherto the teaching of clinical midwifery has been very incomplete. It is not so very long since the attendance at clinics in a maternity hospital was first insisted on. All that the student was called upon to do was to undertake so many cases of labour under the supervision of a hospital or practitioner. He very often had never seen a case conducted in the hospital and when he went out to attend the patient in her own home he had a totally inadequate equipment for the carrying out of a proper antiseptic or aseptic technique. All that required to be changed. It is now necessary for every student to attend clinics in the maternity hospital in addition to conducting cases himself. Our problem to-day is to ensure that the teaching he receives in those clinics and in the hospital is the best he can possibly get. Teaching has been handicapped in the past because a proper allocation of time for it in the medical curriculum was not made. Any odd hour in the day was taken for the purpose, and the student was only in the hospital during the hour of the clinic, when it so very often happened that no cases were available for demonstration. Such a state of matter could

not be allowed to continue Clinical midwifery must be taught in the same way as clinical medicine or clinical surgery The student must come in direct contact with the cases, and he must be given opportunities for examining patients and forming his own judgement upon them This can only be attained by having the student in more or less constant attendance at the maternity hospital over a certain definite period He must be free from other classes so that he may attend at the hospital at any time during day or night when work is going on He must for a definite time live, as it were, in the atmosphere of obstetrics An isolated clinic once or twice a week, or even once a day, over a short period of time is not sufficient The University of Edinburgh has adopted the plan of requiring of every student that he devote one term of ten weeks in his final year to the study of clinical obstetrics, clinical gynæcology, and diseases of children Clinical gynæcology and pediatrics occupy, on an average, not more than one hour a day each, leaving the rest of the twenty-four hours for intensive work in clinical midwifery During this time, in addition to set clinics conducted daily in the maternity, the student must attend a series of demonstrations in the practical room at the University At those meetings obstetrical and gynæcological subjects are discussed by the groups of students under the supervision and direction of one of the assistants They have in opportunity of working with models and instruments, and there is available a representative teaching collection of specimens in the Obstetrical and Gynæcological Museum Groups of students are detailed each day to be on duty at the Maternity Hospital During those days they have the opportunity of seeing all the work during the twenty-four hours

The student's interest is deepened, and the value of the teaching to him is increased, by insisting that short notes be kept of the various clinics he receives the reading he does, and the operations he witnesses Those notebooks are inspected by the clinician at the end of the term, and are awarded a mark in the final summing up of the student's work At the end of the term the student is examined clinically and orally The mark he obtains in this examination, together with that given by the clinician for the character of his notes and his general work in the wards, is added to the mark awarded in the written and oral examinations for his degree His final standing is determined on the aggregate of marks *Such, in brief* outline, is the method of clinical and practical teaching now being carried on in the University of Edinburgh It is not by any means a perfect system, and we are handicapped in various ways in the carrying of it out, especially by the large numbers of students with which we have to deal and by the inadequacy of the teaching accommodation in our *Maternity Hospital It would be* an enormous benefit to the students if small groups could, for a time actually live in the hospital or in a hostel in connexion with it and so be able to take a more active part in the work going on In the planning of any new maternity hospital in a teaching centre this must not be lost sight of

Ante-natal Work

A little more must be said about the character of the teaching in clinical obstetrics That teaching ought to be directed, to a very large extent, to enabling the student to acquire a knowledge of ante-natal conditions and of what may be called preventive midwifery For these purposes the ante-natal clinic should be the principal place of instruction There is no want of clinical material there but the great difficulty in most schools is want of space and proper equipment *If, and when, we get a new maternity* hospital in Edinburgh, we must see that the ante-natal department is large and is planned and equipped in such a way that large numbers of patients can be dealt with quickly The system in vogue at the Tarnier Hospital in Paris, under the direction of Professor Bundeau, seems to me an ideal one A large ward is used for this part of the work It contains about twenty beds or examining couches, each separated from the other by a simple screen When the out-patient arrives she undresses, puts on a dressing gown, and is placed on the examining couch To each patient two students are assigned The student takes the history, makes a general examination, carries out abdominal palpation, measures the pelvis, and makes a diagnosis of the period of pregnancy, presentation, position, and engagement or non-engagement of the presenting part His findings are checked by the clinical assistants, several of whom are always present At a set hour the chief of the clinic passes along, discusses the patients with the students, and thoroughly investigates any abnormalities In this way large numbers of patients can be dealt with in a very short time No patient is overexamined, and yet a very adequate training is given to the students I need not mention the tremendous advantage to the patient herself in that she has not to wait long hours in the clinic Until we get some such arrangement we cannot possibly give our students the training in ante-natal work which they ought to have, and we shall not get all the patients to attend who should

The teaching of abdominal palpation is, to my mind, one of the most important things in obstetrics If we could send out all students thoroughly trained in this method of diagnosing presentation and position, and capable of forming an estimate of the relative size of presenting part to pelvis, we should be doing a great work In the lecture room and at clinics we impress upon them the importance of this examination It is necessary, however, that they have many opportunities of carrying out the actual examination themselves The systematic use of pelvimetry ought also to be thoroughly taught There is a very general feeling among the older practitioners that the taking of pelvic measurements is difficult We must disabuse our students of this idea, and we must see to it that everyone who goes into practice possesses a pelvimeter and knows how to use it A great part of the teaching in the maternity hospital should thus be devoted to clinics and practical instruction on the pregnant woman No student can have too much of that

On a more thorough training of our students along these lines lies our hope of reducing puerperal morbidity and mortality *from obstructed labour* and from untimely and unnecessary interference with normal *labour, from the* toxæmias of pregnancy and from the hæmorrhages The necessity for ante-natal care and supervision is coming to be recognized by a large part of the community Its universal adoption can only come through the effort and example of the whole body of medical practitioners *thoroughly trained* in its details

Before leaving the subject of ante-natal teaching let me also emphasize the necessity for instructing students in post-natal conditions As ante-natal care is preventive midwifery, so post-natal care is preventive gynæcology A properly organized post-natal clinic should be an integral part of every maternity hospital It requires no additional space or *equipment*, as that set apart for the ante-natal clinic can be used for it In such a clinic the student should be instructed in the prevention and treatment of the various disabilities which may follow parturition The importance of this is recognized by all of us, and yet, in most medical schools instruction in it is sadly deficient One of the principal reasons for this is again the want of proper accommodation

The teaching in the hospital itself must be conducted as cases allow One of the very important things is to teach a proper system of aseptic or antiseptic technique, and to that end we must make our hospital technique as rigid as it can possibly be made I have heard it stated that it is no use trying to teach a rigid aseptic or antiseptic technique in midwifery, as it is never possible to carry it out in the patient's own home Such an argument is *most pernicious* I *believe that a* large proportion of the deaths from sepsis in childbirth can be traced to this fallacy It has been said over and over again that *labour* cannot be conducted aseptically—that it is not possible to apply the same principles to the conduct of labour as to the performance of, say, an abdominal operation I absolutely dissent from this view Take, for instance, the matter of preparation of the patient for labour It is the commonest thing to hear it said of a case which has become septic that *every possible precaution* had been taken, and yet we find that the vulvar region had not been shaved What would we think of a surgeon who did the most minor operation on a hair-bearing area without a preliminary shaving of the

part. It is very extraordinary how in this one piece of aseptic technique obstetrics should have lagged so far behind general surgery. As a compromise, clipping of the hair is pretty extensively carried out, but that is a very poor substitute. We have no hesitation in pealing of auto-infection from organisms in the vagina in any case in which this simple surgical precaution has not been taken. As an argument against it, it has been advanced that the patients object. I have yet to meet the woman who, when the necessity for it was explained to her, objected to being shaved. The difficulty of the procedure has been cited. With any form of safety razor it is just as easy to shave as to clip, and there is as little likelihood of causing injury to the patient. I feel perfectly certain that if this simple procedure were universally adopted throughout the country the incidence of puerperal sepsis would be materially lessened. It ensures greater safety to the patient not only during labour but in the puerperium. It renders the nursing very much easier and minimises the danger of the access of organisms to the genital tract in the first few days following labour—a danger which I believe has not been sufficiently recognized. No vaginal examination of a patient in labour should be made before having is done and the vulvar region thoroughly cleaned with some efficient antiseptic. The dorsal position is the one which ought to be adopted for this examination. It only in this position can the labia be thoroughly parted and the fingers introduced directly into the vaginal cavity. Another point in aseptic technique very often neglected is the proper emptying of the lower bowel during the course of labour. In a first labour lasting for twenty hours or longer the initial enema is not sufficient; that enema ought to be repeated every four hours during the course of the labour. Only in this way can we be sure that the lower bowel is emptied of faecal matter and that there will be no escape when the head comes down on to the pelvic floor.

The Conduct of Labour.

During the actual process of delivery in the hospital the same rigidity of technique should be carried out as in the surgical operating room. The compel to field surrounding the patient should be sterile. But it is on the carrying out of the minor details that emphasis should be laid. The students at the delivery ought to be asked to keep their eyes open for any breach of technique. This is one of the best ways in which to develop in them what may be called the aseptic conscience, and it is only when an individual possesses such a conscience that his technique will approach anything like perfection.

After such a training in the hospital we must ensure that when the student attends his cases in the district, he is supplied with a proper equipment so that he can conduct the case with the same care as in the hospital. The hospital should supply him with sterile nailbrush gown, and gloves, sterile towels and swabs, and two small sterile basins. All of these can be packed in bundles with stout cotton cover and carried in a bag together with the simple instruments—such as scissors, artery forceps, hæmatimeter, mucus tube, needles, and antiseptics—required for the ordinary case. The instruments can be sterilized in the hospital wrapped in a sterile towel and covering, and so be ready for immediate use. Instruments can be kept for a considerable time in this way without detriment. He should not attend the case except along with a nurse who is responsible for the preliminary preparation of the patient, administration of enemas, etc. To his first cases he should be accompanied by the extern resident surgeon who sees that all detail is properly attended to. If the student begins his obstetrical work in this way he will attain to a higher degree of surgical technique in his subsequent obstetric practice than has been the rule hitherto. All of this adds considerably to the expenses of the hospital, but it is necessary expenditure. Such a method is carried out in many of the hospitals in the United States and Canada, and in some in this country. Until it becomes universal in all the training of the student will be inadequate, and we cannot look for any great improvement in our mortality and morbidity so far as these are due to sepsis.

If we really face the facts I think we must admit that very often the conduct of labour in the ordinary house falls far short of the surgical ideal. The enormous reduction in the mortality from surgical operations, and the greatly increased scope of operative procedures, are due to three principal factors—rigid asepsis, prevention of all unnecessary trauma to the tissues, and avoidance of shock. These are the three things that are of importance in labour, the neglect of which leads to most of the maternal deaths.

With regard to asepsis I have already gone into some detail so far as the training of the student is concerned. How is the equipment I have mentioned to be provided for the doctor confining the working woman in her own home? At the present rate of remuneration for midwifery cases in general working class practice it is impossible for the doctor or midwife to provide such equipment for each case. One of the recommendations made to the Scottish Board of Health by the Scottish Departmental Committee on Puerperal Morbidity and Mortality is: That local authorities be empowered to furnish on loan, terms, outfit and equipment at a reasonable charge, which should be remitted in cases of poverty. This recommendation if given effect to will go a long way towards solving the problem. The cost to local authorities would be small, for such outfit could be used over and over again after resterilization. Several surgical firms and nursing homes already supply this equipment, but their charges are beyond the means of the working class patient. Here again let me emphasize that the thing needed above all is attention to detail in the use of whatever equipment is provided. It is no use providing a sterile field if the hands, whether bare or gloved, are soiled by contact with non-sterile objects and then brought into contact with the patient's genitals. Soiling of the hands is very often unavoidable when the doctor is single-handed or has inadequate assistance. It is necessary that he have by him a reliable antiseptic solution in which they may be disinfected. I am in thorough agreement with Donald and others who deplore the use of weak solutions of lysol to the exclusion of more powerful agents such as perchloride and biniodide of mercury. One of the greatest advantages in the use of gloves in midwifery practice is that the gloved hand can be more thoroughly disinfected during the course of the labour as a much stronger solution can be used than would be tolerated by the bare hand.

It goes without saying that the fewer examinations made on the parturient woman the less the danger of sepsis. Rectal examination has been advocated instead of vaginal, but even rectal examination not free from danger in these cases where potentially pathogenic organisms are present in the vagina, for in the examination the vaginal wall is pushed up through the cervix and the organisms may thus be directly introduced into the uterine cavity. With the acquisition of greater skill in and the appreciation of the value of abdominal palpation internal examinations or all sorts will become fewer and fewer. Abdominal examination at the beginning of labour reveals the fixation of the head and the exact position of the child. As the second stage progresses descent can be followed until the head is no longer palpable. Very soon after this the pelvic floor begins to bulge and the progress can be followed visually. The ideal way in which to conduct a labour is to make no internal examination at all, or to make only one just after rupture of the membranes to exclude such an accident as prolapse of the cord. If the patient's pelvis has been measured and a vaginal examination made in the later months of pregnancy, and if the head is presenting and fixed at the beginning of the labour there should be no necessity to do more. To make vaginal or rectal examinations simply to satisfy curiosity as to how things are progressing is not justifiable. If we train students and midwives in this way their training can be carried out with a minimum of discomfort and risk to the patients. Such abdominal examinations can be made by several pupils on the same patient, and there should no longer be the necessity of instructing only one pupil can be officially trained on each patient.

Under supervision a small group of students or one pupil midwife can learn infinitely more by thus following cases of labour in hospital than each could possibly do by attending a large number in their own homes. Far too much stress has been laid on the individual at entrance on the outdoor case. To send a student to confine a woman in a poor house, without the assistance of a nurse at the very

worst training possible for him Both should be present, and, in so far as the regulations laid down by the General Medical Council and the Central Midwives Board regarding the number of cases to be attended are concerned, that case should count for both So long as domestic midwifery is practised students and midwives must be instructed by attendance on patients in their own homes, but that should constitute a minor, not a major, part of their training

The avoidance of unnecessary trauma and shock may be considered next It must be part of our teaching that all forms of forcible delivery are attended by both Potentially pathogenic organisms, which would never become active in healthy tissues, may rapidly acquire virulence in bruised or devitalized tissues We all know the high incidence of sepsis in the "failed forceps" case We must teach that such operations as high forceps and version are of the nature of major operations, and must not be undertaken except under such conditions as would be deemed necessary for a surgical procedure of like severity In this matter the public requires educating It is often a difficult thing for a practitioner to persuade a patient and her friends that removal to hospital or nursing home is in her best interests That difficulty will, I am sure, become less and less as doctors see their patients more and more frequently throughout their pregnancies, and so gain their confidence

When we come to consider forceps application in general we reach the crux of the matter so far as midwifery practice as at present conducted is concerned Obstetrics takes up more time in proportion to the monetary return than any other part of the work of a general practitioner He cannot overtake all his work and give adequate time to his midwifery cases—hence the tendency to hurry delivery It seems to me that the solution is to be found in the closer co-operation of the doctor and midwife Such co-operation should include the ante-natal examination of every patient by the doctor, the measurement of the pelvis, the routine examination of the urine, and, two weeks before term, the determination of presentation and position, and the relative size of head to pelvis Under normal conditions attendance at the labour would be undertaken by the midwife, who has the assurance that, on the development of the slightest abnormality, the services of the doctor can be obtained The number of needless forceps deliveries would in this way be reduced, and the forceful delivery before full dilatation of the os and engagement of the head a thing unknown

In such co-operation also lies the hope of a reduction in the number of women suffering from neglected birth injuries The midwife attending a case on her own responsibility hesitates to inform the patient of the occurrence of a tear and the necessity for its repair, unless it is an extensive one That tendency would be minimized by her closer association with the doctor In this matter of the recognition and repair of pelvic floor injuries there is need for more detailed teaching of students It must be demonstrated to them that the absence of external tearing is not proof that an internal tear, involving the postero-lateral vaginal wall and levator ani, is not present, that such a tear can only be detected by careful separation of the labia and digital examination, and that its repair is essential if future disability is to be prevented The proper method of repair must be demonstrated to them in hospital over and over again They must be taught that, whilst every precaution must be taken to prevent lacerations, these are in many cases unavoidable, and that it is no reflection on their skill if they sometimes occur A wider recognition of this fact by doctors and midwives would result in fewer of these cases being neglected One of the findings of the Scottish Departmental Committee on Puerperal Morbidity and Mortality, based on evidence submitted, is that the co-operation of midwife and doctor, in the manner above stated, is a thing to be encouraged in every way

Training of Midwives

Whilst I have spoken mostly on the training and teaching of the student, the same principles apply generally to the training of the midwife Both can and ought to be taught in the same hospital, but they must be in such proportions that a proper training can be given to each In the large hospitals connected with our medical schools the training of students ought to be the first consideration In many of these hospitals the number of midwives trained is so great as seriously to diminish the clinical material available for students From the point of view of the hospital this condition of affairs is justified by the necessity of having a sufficient number of pupil midwives for the nursing of the patients That difficulty would be overcome if obstetrical nursing were made part of the general nursing curriculum in every training school By co-operation between the general hospital and the maternity hospital every nurse could pass through the latter, not training as a midwife, but as an obstetrical nurse I should like to see the time come soon when no nurse will be considered fully trained until she has had such experience The lack of it is a very serious handicap to those of our nurses who may wish to practise their profession in our dominions In Canada, for instance, a nurse with full training in a general hospital here, but with no experience in obstetrical nursing, cannot be registered and is not recognized At the present time a great many of our general nurses train as midwives, not because they have any intention of practising as such, but simply because it is the only way in which they can acquire a knowledge of obstetrical nursing The clinical material used by them would be much better utilized in providing more patients for our students and bona-fide midwives

The Maternity and the General Hospital

The importance of the linking up of the maternity hospital with the general hospital is being recognized throughout the world After a temporary tendency to the separation of obstetrics from gynaecology, these two subjects have again come to be regarded as essentially complementary to each other The one cannot be fully understood without the other, and the practice of both should be in the same hands In Germany the Frauenklinik has been a feature in the teaching schools for many years Very often, however, it was too much of a separate self-contained unit In this country gynaecology has advanced and taken its place alongside general surgery, largely because the gynaecological department has been a part of the general medical and surgical hospital The status of obstetrics in its relationship to the other branches of medical teaching and practice has been very materially raised in the last fifteen or twenty years Its importance, in relation to the general health of the community, is being more fully recognized every day To my mind there is no one single change which will do more to put it and maintain it in its rightful place than the establishment in every general hospital, and certainly in every teaching hospital, of a fully equipped maternity department The obstetrician would then have the advantage of close contact and frequent consultation with the workers in all other clinical departments, and there would also be available for him all the laboratory facilities for investigation and research which are so essential to further advance Such a problem is the toxaemias of pregnancy cannot be solved except by the co-operation of clinical and scientific workers Such co-operation has been extremely difficult in the past owing to the isolated position of our maternity hospitals and the impossibility of providing them with proper laboratory equipment and workers

In Edinburgh the first maternity beds were established in the old infirmary Now when we are faced with the necessity of providing a larger and more modern maternity hospital, I hope that no step will be taken until the advisability and possibility of the closest possible association of that new hospital with the Royal Infirmary has been most thoroughly explored There may be minor difficulties to be faced It is to be hoped that these will not be allowed to overshadow the larger question Edinburgh has a great opportunity now of taking a lead in this matter, and I trust that she will not lightly let it pass

I have been able, in the time at my disposal, to mention only a few of the problems which confront us It may be thought that I have spoken at undue length on the solution of some of them I have done so because I believe that the great need at present is to emphasize the necessity for a more detailed and careful practical application of the principles which we all recognize and accept In this lies our hope for the future

THE CLINICAL USE OF THE SPHYGMOMANOMETER*

BY

K DOUGLAS WILKINSON, O B I , M D, M R C P

ALTHOUGH Harvey announced the discovery of the circulation of the blood in 1628 our knowledge of the circulation did not advance materially until Carl Ludwig introduced the graphic method of studying the heart's action two centuries later He fixed a float to a mercury manometer and arranged so that the movements of the float were recorded upon a revolving drum, and since this the evolution of instruments and knowledge has been rapid Each instrument invented has added something to our knowledge — phrygmographs, polygraphs, electrocardiographs etc — and it is an interesting paradox that the use of instruments of precision in medicine has always (largely because of their educational value) of diminishing the necessity for their use Thus the phygmograph taught us many facts about the pulse which could be recognized subsequently without the aid of the instrument The electrocardiograph was necessary for the detection and explanation of auricular fibrillation, though we now recognize this condition without its aid, and to some extent the same is true of the phygmomanometer

The pulse may be defined as a rhythmic variation of pressures in an artery The highest pressure reached—the systolic—is the result of the output of blood from the left ventricle The lowest pressure—the diastolic—occurs at the end of diastole and is the result of three factor (1) the rate of blood flow through the arteries and arterioles into the capularies, (2) the volume of blood in the arterial system, (3) the action of the muscular and elastic coats of the arteries on the contained blood

The pulse pressure is the difference between the systolic and diastolic pressures The most highly trained finger is incapable of estimating systolic blood pressure accurately and cannot give any certain information about diastolic pressure, indeed, the routine use of the sphygmomanometer will quickly convince anyone that it is useless to expect any exact information about blood pressures from digital examination of the pulse, since the size of the vessel, the condition of its wall, and the force of the pulse may easily lead the finger to form quite an incorrect conclusion as to the pressures in the artery

The best method of obtaining the blood pressures is by *auscultation over the brachial artery, but palpation may* also be used to determine the systolic pressure

After reassuring the patient as to the painlessness of the procedure (this is important because fear is a frequent cause of a raised blood pressure) put the patient as flat as possible and apply the armlet to the upper arm well above the bend of the elbow See that both the patient and the arm are comfortable and relaxed. Apply a stethoscope to the inner side of the bend of the elbow over the lower end of the brachial artery and while listening pump up the armlet At first there is no sound but as the pressure rises a sound appears which is dull and indistinct at first but later becomes loud and clear and then as the pressure is raised further the sound gets softer and finally disappears entirely Now let the pressure fall by just opening the valve on the apparatus the point at which the sound first reappears is the systolic pressure allow the pressure to fall further and the point at which the loud clear sound becomes soft and dull is the diastolic pressure The finger on the radial pulse first detects the pulse beat at a point just below systolic pressure as read by the ear but *the finger cannot estimate diastolic pressure Often the* patient can tell the diastolic pressure for as the pressure in the bag is raised there is a point at which a sensation of throbbing in the arm becomes very evident and this is at or very near diastolic pressure

It is important to realize that an instrument only becomes really helpful when it has been used so often that its use is easy and its fallacies are obvious In no individual does systolic or diastolic pressure remain constant changes of position exercise, food, or drugs produce changes of pressure which are more or less temporary Excitement with its accompanying cardiac frequency always causes a considerable rise of pressure so that it may be necessary to wait until the patient is composed before making an observation of blood pressure

Calcification of arteries, even when considerable in amount, is of little importance as a source of fallacy in blood pressure estimations when more than two and a half inches of artery are compressed, for such a length of artery is never completely calcified The normal artery offers but little if any resistance to compression but when the artery wall is contracted to constrict the artery it may offer a considerable resistance The best way to overcome this constriction is either to massage the limb for a short time or to repeatedly compress and decompress the limb with the armlet

The first reading of a blood pressure is most likely to be fallacious and if immediately subsequent readings show a lower pressure observations should be repeated until a constant reading is obtained The lowest reading is most likely to be correct In any case with a frequent heart action the readings are *likely to be too high and if* possible blood pressure should be estimated during a normal heart rate

A normal child of under 12 years of age should not have a systolic pressure of over 100 nor a diastolic pressure of over 70 mm Hg unless it be very obviously in advance of its years in size or weight In adults the normal systolic pressure varies between 100 and 160 mm Hg and the normal diastolic pressure between 65 and 90 mm Hg and while pressure tends to rise with age there are many old men with quite low pressures Again pressures vary with physique big powerful men having higher normal pressures than their physical inferiors while in women the pressures are five or ten points lower than in men age for age and type for type

At each heart beat the left ventricle forces blood into the aorta and so maintains arterial blood pressure, but the height to which this pressure rises depends upon the resistance of the arteries arterioles, and capillaries and the response that the ventricle makes to overcome this resistance With a normal heart the ventricular response varies directly with the resistance—that is, with the diastolic pressure—and this fact is the keynote of physiological and pathological variations in arterial pressures

When (under experimental conditions) the inflow into the heart is kept constant the output of the left ventricle is unaltered by changes in the heart rate or arterial resistance, but when the inflow varies the heart automatically alters its output to equal the inflow so that in a given time the amount of blood entering the aorta equals that entering the right auricle With a heart rate of 60 per minute the duration of ventricular systole is about three-eighths of a second, so that the heart works three-eighths of the day (nine hours) and rests five-eighths of the day (fifteen hours) G N Stewart calculates the daily work of the heart (ventricles only) at about 150 000 foot-pounds and this is the work of a heart maintaining a systolic blood pressure of 120 mm Hg Prolonged increase in arterial resistance acts as a stimulus to the heart, increases ventricular volume, and, by giving the heart more work, causes hypertrophy

The pulse pressure and the systolic pressure are raised by

1 Excitement nervousness exercise
2 Tonic contraction of the arterial wall such as occurs in asthma migraine etc
3 Nephritis acute and chronic
4 Aortic regurgitation (patent ductus arteriosus and arteriovenous aneurysm)
5 Organic diseases of the arteries senile fibrosis, and arteriosclerosis although a raised blood pressure does not necessarily accompany arterial disease
6 Hyperpiesis—the condition described by *Sir Clifford Allbutt* in which there is a primary rise of blood pressure

The pulse pressure and the systolic pressure are lowered by

1 Loss of peripheral resistance from relaxation of arterioles such as occurs in all atrophic and wasting diseases—phthisis cancer acute fevers especially pneumonia and typhoid.
2. Anaemia from any cause loss of blood (haemorrhage from lungs etc)
3 Cardiac asthenia in Addison's disease and tarrat on
4 Vagus overaction in vomiting attacks collapse and shock

But apart from the detection of abnormally high or low pressures the sphygmomanometer gives us information about the regularity of pulse pressure, and is therefore of

* Read before the Coventry Division of the British Medical Association on December 4th 1923

the greatest assistance in the diagnosis of cardiac irregularities, and indeed it often renders the electro-cardiographic or polygraphic examination of the patient needless, as it enables us to make an exact diagnosis

In auricular fibrillation—important because it is so common, because it often implies grave myocardial disease, and because in certain cases the condition is now curable by means of quinidine—the pulse is irregular in force as well as in time, and in the cases with unusually slowly acting hearts the irregularity may not be easily felt by the finger But when the sphygmomanometer is applied the irregularity is at once obvious by the variation in the sound heard over the artery—a variation which makes it difficult to determine exactly either the systolic or the diastolic pressure, for as the pressure in the bag is raised the more feeble beats are cut out and the heart appears to be less frequent, until at a certain pressure only an occasional beat can be heard There are several facts which may enable us to diagnose the condition without the use of any instrument at all a markedly irregular heart in which the heart rate as counted at the apex is greater than that at the wrist, because the weaker systoles fail to open the aortic valves, or the association of marked pulse irregularity with the disappearance of a presystolic murmur, or the marked slowing of the pulse which usually follows the use of digitalis, and the fact that neither exercise nor atropine as a rule produces either a greater regularity or a marked increase in heart rate

In the form of irregularity known as pulsus alternans the sphygmomanometer may enable us to detect the irregularity before it is obvious to the finger Here the pulse is regular in time but the beats are alternately strong and weak Occasionally there is a slight alteration in time also, and where this is present the longer pause follows the stronger beat In some cases extra-systoles follow every normal beat, so that the pulse waves are felt as alternately strong and weak, but there is always a well *marked irregularity in time, and the longer pause always* follows the weaker beat, or, to put it in another way, the pulse is felt as two beats, the second of which is the weaker, and a pause Except in the alarm that they occasion in the patient these extra-systoles are of no importance The true alternating pulse is always indicative of a very serious condition, it is found in advanced cases of myocardial disease, in renal disease, and in advanced arterio-sclerosis, it is sometimes discovered in acute diseases such as pneumonia, typhoid, or influenza, and may be the only discoverable physical sign in patients with angina In my experience this form of pulse irregularity always implies an early fatal termination of the condition in which it appears

The pulsus paradoxus is the pulse irregularity which is commonly associated with pericardial effusions In this irregularity there is a failure of pulse volume during inspiration, so that at each inspiration the pulse either disappears entirely or becomes reduced in size A slight degree of this irregularity is produced by quite small effusions into the pericardium, but such slight irregularity may be quite imperceptible unless it is sought for by means of the sphygmomanometer Although the pulse pressure appears to be quite regular to the finger in such a condition, when the armlet is applied and the pressure in it is raised to near the systolic pressure the sound will be heard to vary markedly in intensity, being louder in expiration and softer or absent entirely during inspiration Pericardial effusion may be particularly difficult to detect, and this sign is often of assistance in doubtful cases Conditions which interfere with the inspiratory negative pressure in the thorax can also produce this pulse irregularity A large pleural effusion, whether of gas or fluid, may lead to the paradoxical pulse, and in the war this irregularity was fairly commonly found in men with wounds of the chest, especially those in whom there was a large wound which allowed free ingress and egress of air to the pleural cavity at each respiration Some children also show a slight degree of this irregularity of pulse volume in association with the juvenile type of irregularity in which the heart rate quickens during inspiration and slows during expiration

In heart disease severe heart failure may take place without any noticeable change in blood pressure, for the heart will maintain the blood pressures at or near the normal even when its output per beat is insufficient to ensure an efficient circulation As Sir T Clifford Allbutt says, "the heart dies sword in hand" But sometimes we can recognize impending heart failure in changes in blood pressure In cases of hypertrophy, renal disease, or arterio-sclerosis in which there has been a high pressure for years, a fall in the systolic pressure without any change in the diastolic pressure is significant, and whether it be associated with an increase in distress, or with dyspnoea, or appear alone, such a change in pressures is to be regarded with apprehension It has recently been shown that the higher the diastolic pressure the greater must be the pulse pressure for the same diastolic output per beat, so when a patient with a high diastolic pressure shows a fall in systolic pressure without any corresponding fall in diastolic pressure the output of his heart per beat is less, and, except there be a corresponding increase in pulse rate, his circulation is already beginning to fail This fact shows the importance of reading the diastolic pressure as well as the systolic

One of the well known signs of aortic regurgitation is the collapsing pulse, which was described by Corrigan ninety-two years ago—its peculiar character being due to the combination of a raised systolic pressure and a lowered diastolic pressure In adults with aortic incompetence the systolic pressure is always above 120 mm Hg, and the diastolic pressure is usually below 65 mm Hg Often it is very difficult to ascertain the exact diastolic pressure, as the pulse sound is loud even when the pressure in the armlet is at zero Sometimes the sound heard over the artery is so loud that it resembles a pistol shot

There is another curiosity in the arterial pressures in aortic disease which was first described by Professor Leonard Hill In a normal individual standing up the arterial *pressure in the leg* at the knee is higher than the pressure in the arm at the elbow by the weight of a column of blood equal in height to the distance from the knee to the elbow, but when the normal man lies down, the pressures in arm and leg soon become approximately equal On the other hand, in the great majority of cases of aortic regurgitation, when the patient is lying flat the pressure in the leg is considerably higher than that in the arm The suggested explanation is that, in order to maintain a good supply of blood to the brain when the patient is erect, those arteries in which blood flow is retarded by gravity (those above the level of the heart) are completely relaxed, while those arteries in which the blood flow is assisted by gravity are in a state of tonic constriction, and that this spasm persists even when the patient is lying flat In observing the leg pressures the armlet (or leglet) should be applied just above or just below the knee, and the stethoscope is applied either over the popliteal or posterior tibial artery It is important to have a bag of sufficient width, as too narrow a bag gives high readings The width of the bag should be about a quarter the circumference of the limb

While this peculiarity is not invariably present in aortic regurgitation there is usually a difference of 30 mm Hg between the systolic pressure in the arm and leg The severity of the valvular lesion may be gauged by the pulse pressure—the higher the pulse pressure the worse the lesion, but if the diastolic pressure is 70 or more it is certain that the amount of the aortic regurgitation cannot be serious

In hemiplegia from a cerebral haemorrhage the pulse pressure is always high, while in a thrombosis the pulse pressure is less than the normal for the diastolic pressure If the hemiplegic is found to have a high and rising pulse pressure he is sure to die of his haemorrhage, or if the pulse pressure is low and falling he will die of his thrombosis As an example of this statement I will quote a case, a man of 57, who had extensive arterial disease and a large heart His blood pressure was 200/140 (Note that the normal pulse pressure for a diastolic pressure of 140 should be about 120 mm Hg, while here it is only 60 mm Hg, so that the systolic output of the heart must have been considerably reduced) The patient had several cerebral

accidents, and finally succumbed The post mortem examination showed a very extensive cerebral thrombosis

In enteric fever there are two accidents which it is often difficult to differentiate—perforation and haemorrhage In the former a rise of blood pressure occurs after the primary shock, but in the latter the fall of blood pressure is always very marked and prolonged

In pneumonia a rise of blood pressure before the crisis is often the first sign of some complication, while a fall may indicate impending heart failure

Finally, blood pressure observation may be of considerable assistance in cases of albuminuria, a high blood pressure indicating renal disease—either a nephritis or that type of renal damage which results from hypertrophy of arteriosclerosis In pregnancy the sphygmomanometer may be especially helpful, for it is often difficult to decide how much importance should be attached to a small amount of albumin in the urine of a pregnant woman The normal systolic pressure of a woman of about 30 of average physique is about 112 mm Hg A pressure of over 130 would suggest the need for careful and frequent examination and a pressure of over 150 would probably indicate the onset of eclampsia

I do not think that a blood pressure of over 160 systolic or 90 diastolic is ever normal, although there are cases in which the diastolic pressure remains about 100 for a time without any certainable cause and then returns to normal limits Excitement may cause such considerable rises of pressure that it is well to bear in mind the fact that a high pressure is of greater significance when accompanied by a slow pulse

CHRONIC INTESTINAL STASIS AND EPILEPSY

A WHITE ROBERTSON, L R C P and S Edin
LONDON

In the study of epilepsy it seems clear that whatever the actual exciting element the vascular system is the main source of the epileptic phenomena, either alone or as a carrier of toxic agents, and the work that has been done experimentally by the advocates of both views has been very considerable in the last twenty years Cells cut off from their circulation, even momentarily show a reaction towards acidity, and this acidity factor must not be lost sight of in the interpretation of the experimental results recorded by the mechanical and vascular theorists Faradization and epinephrin will also blanch pial vessels and produce epileptiform convulsions The proteoses of Cuneo to be presently described, have the same effect when painted on the cortex Lastly, lactic acid given intravenously will also produce convulsive seizures Acidosis, therefore whether produced locally or remotely, would appear to play a considerable rôle in the production of the epileptic convulsion and the work of Cuneo during the last nine years at Genoa goes perhaps further than that of any other investigator to establish its importance

Cuneo established the presence in the blood of persons who had just had an epileptic seizure of a substance which he identified with the proteoses and this substance introduced intravenously into animals faithfully reproduced the epileptic phenomena At the same time he showed that the urine of these persons contained an extraordinarily high percentage of organic acids Other features were a retention of total nitrogen, an increase in the nitrogen content and continuous acidity of the faeces Comparative tests in epileptic groups with a protein rich and with a carbohydrate pure diet next gave unexpected results, the acidosis in the former group being reduced with a corresponding improvement in the severity and number of the fits, whilst there was a percental increase in acidity in the second group, and the fits increased in number and severity It was next established that the fault in the starch metabolism occurred in the first stage of conversion to the disaccharides, maltose, lactose cane sugar, etc Normally this takes place through the action of the amylolytic ferments, the subsequent conversion of maltose being effected by maltase ferment through hydration into glucose The failure in the first stage resulted, in the absence of sufficient amylolytic ferment, in the production of a more or less intense concentration of organic acids—acetic, butyric, lactic, tartaric, etc —and these, which should normally have been united with all alimentary bases in the small intestine, passed in the epileptic into the blood stream and urine unchanged The alimentary salts in normal individuals are oxidized—if ammoniacal through ammonium carbonate into urea if sodium into sodium carbonate and this is the vitally necessary salt for maintaining the alkalinity of the blood and tissues Cuneo concludes from his work that this transformation of organic salts into sodium carbonate begins in the mucosa of the small intestine and is completed in the liver whence the sodium carbonate is returned to the gut with the bile Lack of bases favours the production of acidosis while a sufficiency of sodium tartrate favours the activity of the liver ferments and the production of sodium carbonate It sodium acetate or tartrate is introduced directly into the circulation it causes typical epileptic convulsions and Cuneo was able to remove from the carotid artery of the animals used a substance which proved to be a proteose

The source of these proteoses Cuneo found in the reduction of that fundamental constituent of all cellular nuclei nucleo-histone and in the case of the serum and leucocytes of the blood also this reduction takes place under conditions of acidosis due to the concentration of organic acids In an acid medium he was able to demonstrate the reduction of nucleohistone from both these sources into an innocuous acid and a toxic base having the chemical and biological properties of nucleinic acid and of proteose Introduced intravenously in dogs the latter not only produced typical epileptic convulsions, but the *post-mortem* appearances in dogs dying in status epilepticus so induced were identical with those found in the viscera and the brain and its coverings in persons dying of proteosaemia (albumosaemia), and as described by Tanzi and Lugaro in their findings in patients who died in typical status epilepticus

He believes that albumosaemia exists in epilepsy and that this is caused by an insufficiency of the alkali forming function in the liver and the small intestine, so that the acid organic salts which are transformable into sodium carbonate do not undergo this metabolic change, but enter the circulation and cause a division under certain conditions of the nucleo-histone element and the nucleo-proteins into nucleinic acid and proteoses These latter remain free and exhibit their convulsive action

Localized acidosis in derangements of the circulation may also set free albumoses or it may be other toxins, as in Jacksonian seizures and in the convulsions associated with cranio-cerebral injury with scar adhesions, brain abscesses circumscribed areas of encephalitis brain tumour cysts general paralysis cerebral arterio-sclerosis, the acidosis produced by interference with the vascular supply may as suggested by Professor Onato determine the release of proteoses locally in cells cut off from their circulation and so excite the convulsions associated with these conditions In general paralysis and arterio-sclerosis and probably also in encephalitis the vascular disturbances and the local cellular destruction processes in the brain elements are ideally combined to produce generalized convulsive seizures

A little over two years ago it was my privilege to address you on the possibility of proving a close connexion between epilepsy and chronic intestinal stasis More recently I have published a preliminary report on a small group of epileptics treated on lines directed exclusively to the relief of the gastro-intestinal conditions found associated in these patients with the epileptic phenomena To-day thanks to Cuneo's researches I find myself in a stronger position to press the importance of chronic intestinal stasis as a

In address to the Tunbridge Wells Division of the British Medical Association February 27th 1924

factor in the pathogenesis of epilepsy I have had opportunity of studying in very great detail 27 cases of epilepsy In all of these a full personal and family history was *obtained, and each patient was examined, system by* system, for indications of history of chronic toxic conditions The blood, menstrual blood, urine, and stools were examined, and the condition of the uterus, urinary bladder teeth, tonsils, nares, and sinuses investigated Thirteen cases were x rayed with bismuth meal and barium enema, and eight of these were operated upon for conditions of advanced stasis affecting the general health In every epileptic examined the clinical and laboratory evidence was eloquent of considerable chronic intestinal stasis and widespread mucosal catarrh of the intestine, as described first by Lane As in the early group reported, treatment has been directed in every case primarily to the relief of the intestinal condition

Of the 27 cases examined, only 20 can be reported upon is still under my personal supervision, and of these 5 have not been sufficiently long under treatment to enable me to include them in any statement of results I can, however, report on 15 cases sufficiently long under treatment to be included in such a return

In 5 cases there has been complete arrest of epilepsy over a period of from one to three years, 3 other cases show immunity over a period which just [illegible] in into the same category, 3 cases show a [illegible] and decrease in severity of the attacks, 3 c[illegible] with some injury to the scalp from burns, show no improvement at all, one case died from pulmonary embolus following operation

When it is remembered that bromides and luminal have been excluded from the treatment, and that the carrying out of my instructions has been in many and various hands, I think that I may fairly claim that the methods of treatment I have adopted have yielded results which go some way towards proving a close association between demonstrable chronic intestinal stasis and epilepsy

The following points have emerged in the examination of cases

The faeces were examined in all for intestinal parasites and their ova, with negative results Fourteen cases showed undigested starch in excess, and practically all cases showed an acid reaction in the faeces Bacilluria occurred in 15 cases, albumin in 4, sugar in 1 and the average total acidity of the 27 cases was considerably above normal The blood pressure readings varied under 100 mm , 4 under 110 mm 2, under 120 mm , 6, under 130 mm , 5, under 140 mm , 2, 150 mm or under, 4 So that the average was 121 4 mm The pulse pressure averaged 43 2 mm Of 11 females 4 showed definite goitre, and 4 marked amenorrhoea Tonsils were found enlarged and septic, or had been already removed, in 12 cases In one case a suppurating antrum had been treated Sixteen cases gave definite evidence of chronic catarrh of mucous membranes other than the gastro intestinal tract Enuresis was reported in 4 cases sleep walking in 4, urticaria in 7, stammering in 3, migraine in 3 asthma in 1 A family history of epilepsy was found in 8 stammering in 8, asthma in 3, migraine in 3, urticaria in 2, chorea in 1 In no case was a syphilitic history obtained either in the patient or in the parents In 2 cases the parents were first cousins Congenital defects or malformations were found in 5 cases undescended caecum in 1 maldevelopment of the genital organs 1, persistent deciduous teeth 1, hypoplasia of enamel 2 impacted molars 2 there was a personal history or active tubercle in childhood in one patient, and in one case the family history showed tubercle involving three members of the family, whilst in another case there was a family history of chronic alcoholism in the father

The results of treatment generally have been, I think, encouraging, and if all the operational cases have apparently not done better than the unoperated group, it must be remembered that these were cases calling definitely for operation on the grounds of intestinal stasis alone, and, further, that with the two exceptions where colectomy was done, the removal of a controlling appendix and acquired bands or adhesions still left the oedematous, turgid, congested and perhaps denuded mucosal surfaces for after-treatment Were not colectomy so dangerous an operation I should be inclined to resort to it more frequently in epilepsy but as a general rule the treatment of cases not operated on, or otherwise operated on, is necessarily prolonged and results cannot be expected at once in cases of long-standing chronic mucosal catarrh Yet the immediate cessation of epileptic attacks from the date of operation in several cases has been a very striking experience

There is much to investigate in every individual case, besides the degree of involvement of the colonic tube The extension of the chronically catarrhal and infective processes to the duodenal and upper jejunal area, and to the stomach, is a common feature in all cases of intestinal stasis at all advanced, and it is this extension which links my observations with those of Cuneo I believe that the leaking septic tank is the first cause of epilepsy, and that the later involvement of the small intestine and liver in chronic intestinal stasis is the next step towards the failure of the alkali reserve which Cuneo has described And I further believe that the graver the involvement of the mucous membranes of the body generally, but particularly of the colon, in the chronic catarrhal processes, the greater the output of organic acids and the more profound the demineralization of the tissues and cells of the body Acidosis is the feature of epilepsy, and is associated with persistent acidity or hyperacidity of the faeces and urine In the presence of such an acidosis the destruction of the nucleo-histone of mucosal cells is constant and widespread, and proteosuria results on a huge scale independently of the actual pressure of organic acids in the blood stream itself I am confirmed in this view by the constancy with which my patients attribute their attacks to indigestion, to constipation, or to the presence of offensive stools, and by the good results of a return to sound habits of colonic hygiene It is also my experience that the more chronic and extensive the colonic catarrh the more grave the epilepsy in severity and frequency Moreover, the more rigorously the system of treatment is carried out the more rapid and complete the improvement This treatment is directed to the restoration of the function and amenity of the gastro-intestinal tract, and particularly to the reduction of the septic catarrhal process, but no treatment will prove successful which does not also provide for a vitamin-rich diet, for remineralization, for endocrine and general hormone reinforcement, and for the removal of septic processes wherever recognized Where surgical relief of stasis is obviously necessary it must be carried out

The part played by heredity is still a matter of dispute, but the figures I give in my own small series are sufficiently striking, not alone for epilepsy, but for the closely allied explosive conditions — migraine, stammering, chorea, asthma, and urticaria Sargent reviewed over 18,000 cases of cranio-cerebral wounds with skull defect resulting from war injuries Of these about 800 only, or 4 5 per cent, developed epilepsy I have, in the last five years, made a complete clinical and laboratory examination of no fewer than 500 cases of typical chronic intestinal stasis, yet of these only 27 have shown any signs of epilepsy—say 5 per cent In these 500 cases are many showing varying degrees of other nervous conditions—nervous exhaustion, phobias, borderland cases, dementias, sclerosis, etc But, unless the vulnerability of the cortex to certain specific toxins in certain individuals or families is accepted, we have no other explanation for the very occasional appearance of epilepsy in a condition so common as acidosis All our present experimental methods of inducing epileptiform convulsions in laboratory animals—as tetanization, artificial anuria or acidaemia, painting the cortex with epinephrin or proteoses, etc —fail to explain the general immunity of the vast majority of people to the epileptiform convulsions so induced in laboratory animals I, too, like Professor Osnato am convinced that it is on the lines of Cuneo's work that the great advance is to be looked for My own work on stasis offers, as explanation of the failure of starch reduction in the small intestine which he has described in epileptics, the fact that extension of the catarrhal processes to the upper small intestine from the colon is due to mechanical obstruction at the ileo-caecal entrance and at the *duodeno-jejunal* junction secondary to overloading of the static colon Another factor must surely be the subversion of the hepatic functions by the high acid and toxin content arriving by the portal channel There is, however, this also to be said the destruction of mucosal cells in the colon on a wide scale in stasis releases into the vascular system toxic agents which, coming from such an origin, must have a specific affinity for mucosal cells at a distance Only thus can we explain the frequency and the chronicity of catarrh of remote mucous membranes—nasal, bronchial, uterine—which is so constant a feature in chronic stasis cases, and

which proves so intractable until the main colonic reservoir of these toxins is overhauled and repaired. Closer study of the leaking septic tank will yield a most fruitful contribution to medical science and a further step to the solution of many problems hitherto accepted as insoluble. These will almost certainly include a large proportion of chronic functional disorders within the province of neurology and psychiatry, and with them the problem of epilepsy will never be advanced definitely nearer to complete solution.

I have to acknowledge gratefully the loyal support and co-operation of the many general practitioners who have carried out my suggestions in treatment and the staff of the various hospitals and homes where operations have been performed. I. T. Dr. A. C. Jordan and to Sir W. Arbuthnot Lane especially my thanks are due for the great skill and interest the latter has shown in the X-ray and operational sides of the work.

[illegible]

British Medical Association

PROCEEDINGS OF SECTIONS AT THE ANNUAL MEETING, BRADFORD, 1924

SECTION OF LARYNGOLOGY AND OTOLOGY

W. JOBSON HORNE, M.D., President.

IMPORTANCE OF EARLY TREATMENT OF ACUTE OTITIS

BY

JOHN F. O'MALLEY, F.R.C.S.

Surgeon, Ear, Nose and Throat Department, University College Hospital, London.

EVEN in comparatively recent years among the general public there was a tradition which has not yet died out completely, that ear affections are incidents in the lives of individuals, largely controlled by age periods, such as seven or fourteen years, at which times those afflicted were supposed to "grow out of it." It was believed that ears which discharged were safe whilst they continued to do so, on the principle, I suppose, that it was "better out than in," and became dangerous only when the discharge ceased to appear. Pain in the ear was to be soothed by poultices or laudanum drops, until discharge made its benign appearance to relieve the patient's distress, after which the condition was frequently left to *vis medicatrix naturae* and the doubtful consolation of "growing out of it." All this is being gradually changed, and I look to the various child welfare centres and clinics now at work to dispel finally this *laissez-faire* attitude, but they need guidance from some authoritative source on the present otological view of the whole subject. It should be the object if not the express duty, of meetings of this kind to take a large share in such educational work.

The importance of acute otitis, whether catarrhal inflammatory or suppurative can be put in many ways to convey its true significance to those members of our profession not immediately concerned with the specialty of otology, but I hope you will not consider it is overstating the case to say that fully 90 per cent. of the common and most serious ear affections come within its ambit, if we include all the possible complications and sequelae of otitis media. The term "acute otitis" may be appropriately applied to any acute inflammatory or suppurative process arising in any portion of the organ of hearing whether external, middle, or internal ear; however in the usages of everyday practice we limit the term to affections of the external and middle ear only and refer to those of the inner ear as labyrinthitis, though the latter is due to an extension of disease from the middle ear or its adnexa, with the one exception of cerebro-spinal fever. External and middle ear inflammation expose the function of hearing to the risks of partial or complete destruction, their complications and sequelae not only intensify the evils but are frequently dangerous to life and sometimes prove fatal. Acute otitis of the outer ear usually takes two forms, the circumscribed and the diffuse, the former being the more common. Neither is dangerous to life but may be to hearing since if neglected or not treated with care perichondritis of the pinna and cartilaginous meatus may set in terminating in necrosis and occlusion of the passage. Circumscribed external ear inflammation with its associated oedema in many cases assumes a special significance, inasmuch as it may be confused with mastoid extensions of middle ear infection. This is a pardonable error for the inexperienced to make at times, the error being [illegible] if the rare condition is diagnosed for the simpler than it is.

When we come to consider an acute affection of the middle ear the gravity of the outlook is very different since an acute inflammatory process in such a small air chamber clothed with a vascular lining and containing a delicately jointed bony chain for the conduction of sound constitutes a dangerous menace to the function of hearing. If the middle ear were a cavity constructed on the lines of the antrum of Highmore one would expect an inflammatory infection of its lining to be self-limiting and ending in nothing more serious than an empyema capable of easy drainage and cure, but the possibilities of extension of disease from the middle ear to the cranial cavity through the labyrinth or by the mastoid antrum and air cells to the meninges and lateral sinus are so very real that no effort should be spared in combating the earliest manifestations of the infection to cut short the attack.

Let me briefly recall the formidable array of possible complications and sequelae of acute otitis to emphasize the claims made for the importance of the subject and the need for its early and proper treatment.

1. Acute otitis externa. Perichondritis, necrosis or cartilage, occlusion of meatus, deformity and pain.
2. Acute middle-ear catarrh. Eustachian block, impaired ventilation of middle ear, retraction of membrane, impaired movements of ossicular chain, tinnitus, chronic middle-ear catarrh, various grades of deafness, progressive deafness and internal-ear deafness.
3. Acute purulent otitis media. Acute suppurative mastoiditis, lateral sinus thrombosis, extradural abscess, brain abscess—cerebral or cerebellar, acute labyrinthitis—diffuse or circumscribed, and purulent meningitis.
4. Acute serous labyrinthitis.
5. Acute diffuse suppurative labyrinthitis, which may cause extradural abscess, cerebellar abscess, purulent meningitis, lateral sinus thrombosis.

In addition to these intracranial lesions there are many possible intratympanic ones, such as:

1. Perforation and partial or complete destruction of the drum head depriving the tympanum of its air-cushion effect in the conduction of sound and exposing the cavity to a new route of infection.
2. Arthritis and ankylosis of the ossicular chain with impairment or mobility.
3. Necrosis of ossicles with destruction of their function as a conducting mechanism, probably the commonest intratympanic cause of middle ear suppuration.
4. Ulceration of tympanic lining with caries of bony wall and formation of polypi.
5. Scarring and adhesion in the tympanum impeding the conduction of sound and the drainage and ventilation of the cavity, increasing the difficulty of rendering it free from epithelium and also making it more prone to further infection.
6. Necrosis of the posterior tympanic wall, invasion of the Fallopian canal with neuritis and paralysis of the facial nerve.
7. Various grades of deafness.
8. Deaf mutism.

Over 60 per cent. of all ear diseases are middle-ear diseases. Apart from the personal affliction, deafness has a large economic side. The partial or complete destruction of such an important educational portal as that of hearing deprives the person of the power to acquire knowledge by sound, with two obvious results: (1) incomplete and inefficient education, (2) inability to fill occupations where communication on

by sound is an essential qualification, which means nearly every walk of life There is the further economic handicap that insurance companies debar persons with certain chronic ear affections

So much for the importance of acute otitis as measured by its ravages, now for the urgency of early treatment Details of treatment are outside the scope of this discussion, but if it is to bear any fruit we must give some indication of a better line of action than the old expectant attitude

We must begin with the young Hearing in children is very acute and far in excess of their needs, so that any deafness indicates a serious lesion and requires immediate attention The foundations of deafness are laid in childhood and even in infancy In an aural clinic one is constantly coming across tympanic membrane or cavity lesions of a gross character, of which the possessor or those responsible for his or her health in early life have no history to give The obvious inference is that an acute ear trouble occurred at an age prior to the patient's recollection, probably in association with some other serious illness, and was not observed by the parents or the medical attendant Such cases could not occur if we followed the dictum urged by Kerrison, when he says that "he firmly believes the routine practice of examining the ears of all sick children would prevent not only much unnecessary suffering but also some loss of life"

When lesions of a suppurative nature, the sequelae of acute affections with outstanding symptoms, can escape notice in this way, what chance of receiving early attention have the mild onset and changes of middle-ear catarrh? Yet from the number whose impairment of hearing results from a simple middle-ear catarrh, so common in incidence, insidious in onset, and progressive in deleterious action, without any compelling symptom to send the patient for early advice, we know that it is far more serious as a cause of deafness than the acute suppurative conditions Acute affections attended by pain or discharge will always claim their meed of attention and early treatment, but by the time that middle-ear catarrh has revealed itself by its only manifest symptom, deafness, the earlier stages will have long passed over

When I was aural surgeon at the Evelina Hospital for Sick Children some years ago I made a point of examining the ears of every child brought up for the tonsils and adenoids operation, independently of any history of deafness or earache, and noted any changes to be seen in the drumhead Every child who was prone to recurring colds and had a moderate or large amount of adenoids or large tonsils showed membrane and middle-ear changes, even without any question of deafness These manifestations of middle ear infection are, in my opinion, the forerunners of many of the non-suppurative cases of deafness so frequently met with in adult life and for which we are unable to find any cause in their recent history Any alteration in density, colour, lustre, or cone of light promptly settled my decision in favour of operation for the removal of tonsils, if large or septic, adenoids if present and the necessary treatment of the nose if obstructed These alterations in the appearance of the membrane one has interpreted as evidence of intratympanic infections, and the retraction as an indication of *impairment of ventilation of the middle ear cavity* Only a routine examination of the ears in all children will enable us to get at the early treatment of middle-ear catarrh so as to prevent the deafness which follows years later on tympanic infections in childhood

If a procedure of this sort were adopted I feel that the incidence of non-suppurative deafness in adult life would be very materially mitigated, and otologists would escape much of the reproach that "they can do so little for this form of deafness," when as a matter of fact much of it, which is impossible to cure when fully established, could have been prevented

Now for the early treatment of the more acute conditions, which for practical reasons I will group as follows

1 Deafness and pain with hyperaemia of the membrane, indicating a tympanic infection and acute inflammatory reaction

2 Deafness, pain, hyperaemia, and bulging of the membrane, the serous secretory stage of No 1

3 Acute middle-ear suppuration, the purulent stage of No 2

4 Nos 2 and 3, with suspected mastoid antrum infection

Our position here is not clear, and we are faced with a problem similar to that which confronted general surgeons some years ago with regard to appendicitis—namely, were cases to be treated on purely medical or surgical lines or when was surgery indicated? At that time a well known surgeon made the arresting statement "that a man suffering from appendicitis was in as grave danger as if he were sleeping on the brink of an active volcano" Osler, as far back as 1895, in his textbook said, "There is no medicinal treatment of appendicitis" I am convinced that every surgeon of experience will grant the applicability of Osler's assertion in the case of mastoiditis, but how about acute middle-ear suppuration with or without mastoid antrum infection? Is the treatment to be medicinal and for how long, or, if surgical, how soon and what form should it take? These are questions on which we must make up our minds for the guidance of those who are brought into contact with the cases in the first instance

Should the removal of tonsils and adenoids be regarded as an essential part of early treatment, and how soon after the onset of middle-ear suppuration ought the operation to be performed? Shall we drain the tympanum surgically, and, if so, should this be through the meatus only or in addition, when cases show no definite signs of mitigation of discharge or improvement in hearing, resort to post auricular drainage through the mastoid antrum? The results of the latter procedure have been so uniformly satisfactory in early cases of mastoid with middle ear suppuration in promptly arresting the tympanic condition that its ease of performance and freedom from risks in the hands of any skilled person should commend its early adoption, even in the apparently uncomplicated cases of otorrhoea, long before these could pass into the chronic stage

DISCUSSION

Dr PETER MACDONALD (York) expressed the opinion that there was urgent need for inducing the general practitioner to recognize that delay, sometimes only of hours, in active treatment of acute otitis media was dangerous No general practitioner was competent to deal with a condition which might be acute otitis media unless he was able not only to examine the ear with thoroughness—often a difficult matter—but also to make an immediate decision whether operative interference, such as myringotomy, was called for

Sir MALCOLM WATSON (Federated Malay States) emphasized the fact that although the discussion was being carried on by specialists their words would go out to general practitioners, to whom this was a most important subject

Dr WILLIAM HILL (London) pointed out how necessary it was to instruct the general practitioner how to examine the ear properly He thought that school medical officers did not examine the ear *qua* ear so well as they ought to do, in contradistinction to their care in examining the throat and nasopharynx for enlarged tonsils and adenoids

Dr J S FRASER (Edinburgh) said that the differential diagnosis between furunculosis of the meatus with retro-auricular swelling on the one hand, and mastoiditis from otitis media on the other, was difficult, not only for the general practitioner, but also for the specialist He himself had made mistakes on several occasions, but he thought that if diagnosis was difficult or impossible it was better to treat the case as one of the more serious condition and to open the mastoid It was remarkable how many people had forgotten that they had ever had middle ear suppuration, and supposed it was due to the fact that *none* of them could remember things that had happened during the first four years of life He called attention to the fact that some cases of acute suppurative otitis media went on to meningitis at a very early date, even when there was no

labyrinthitis In such cases it was difficult to be sure of the route of infection It might be by way of the blood stream, thus, in the presence of otitis media the organisms in the blood settled down in the subarachnoid space and produced meningitis On the other hand, the infection might pass by way of the fossa subarcuata from the inner wall of the mastoid antrum beneath the dome of the superior canal to the posterior fossa Dr Fraser also called attention to the economic incidence of chronic middle ear suppuration This was very frequent in hospital practice and rare in private practice, the reason was that wealthier and better educated people did not allow an acute middle-ear suppuration in their children to become chronic—they had it efficiently treated when it was acute Dr Fraser did not advocate paracentesis before bulging of the drumhead (stage 1) carbolic and glycerin drops should be used along with general treatment After suppuration the dry method should be recommended at least in hospital practice, and even in private work if the mother or nurse were competent

Dr W H KELSON (London) thought that when the general practitioner saw a red swelling at the end of the meatus he ought to recognize that that case had passed out of his hands into those of the specialist

Mr C A SCOTT RIDOUT (Portsmouth) believed that this question was not taken seriously enough by the general public, especially in schools—not only elementary schools but public schools He thought the idea held by many general practitioners that a running ear should not be syringed ought to be combated The general practitioner should be taught that an acute middle ear inflammation required the surgeon as much as did an acute appendix

Dr F H WALLACE (Uppingham) suggested that Mr Scott Ridout's views were unnecessarily gloomy as regards the public schools He knew from personal experience that aural conditions were certainly taken seriously not only by the medical officer, but by the *matron and others* responsible

Dr NEIL MACLAY (Newcastle-on-Tyne) said that with regard to the first stage of acute otitis media he was of opinion that early incision of the drumhead was of the *greatest importance and so long as one was satisfied that* the condition was middle ear inflammation and not simply a myringitis and part of an external otitis he thought the membrane should be incised prior to evidence of bulging In those cases where there was a post auricular swelling, and where there was difficulty in determining whether that condition was due to mastoiditis or furunculosis, he thought it was better to expose the bone and be prepared to proceed to the opening up of the mastoid and area if necessary X-ray examination in those cases might give valuable assistance in arriving at a correct diagnosis When discharge had taken place in the acute ear he was in the habit of treating the case by the wet method He advocated syringing out the ear canal in order to remove discharge and debris so that drainage might be facilitated Epithelial debris was very apt to accumulate in such a way as to block up the opening in the drumhead and it seemed to him that the only way by which the debris could be successfully removed was by means of the syringe The risk of introducing fluid into the middle ear need hardly be considered when one remembered the relatively small size of the perforation and the condition of the middle ear cavity resulting from its swollen mucosa

Mr F HOLT DIGGLE (Manchester) thought the question *of an early paracentesis in those cases which presented a* congested membrane but no bulging was a difficult one to decide All of them had had cases cured without paracentesis The density of the membrane had so much to do with determining whether there was early bulging or not Dense membranes resisted bulging for some considerable time, and Mr Diggle considered that the all important point was pain In his opinion if pain persisted for forty-eight hours without bulging the membrane should be incised The fortunate cases as regards preservation of hearing and early cessation of discharge were those which presented an early mastoid abscess, since the mastoid was of necessity opened early They were all familiar with the good results obtained in these cases, such good results should not deter them from opening and draining the mastoid antrum in cases where the otorrhoea persisted in spite of skilful early treatment Mr Diggle found it very difficult to decide clinically whether the mastoid was involved in those cases of profuse persistent otorrhoea without any tenderness or pain over the mastoid He had not found x rays of much value in deciding this question and therefore considered that in these cases the mastoid should be opened and drained if there was no improvement after ten days *If the mastoid* was not opened these cases lingered for several weeks and perhaps ultimately cleared up, but almost invariably with some impairment of hearing if not a permanent perforation of the membrane He believed that the bacterial type of infection was important, as he had found that practically all streptococcal and *influenzal cases required early drainage of the mastoid* antrum even when the usual external signs of mastoiditis were absent

Mr DIXLOP thought that syringing was good treatment if performed properly, but the ordinary syringe used by the *patient was a bad one for the purpose*, especially in unskilled hands

Mr H BELL TAWSE (Nottingham) said that he rarely performed paracentesis of the drum, his first association with the case being usually after the drum had ruptured Enlargement of the perforation for effective drainage was occasionally necessary In the cases with free discharge, no pyrexia, no pain, no mastoid tenderness or swelling and no adenoids, he advised very frequent fomenting of the inflamed drum with the warmest sterile water the patient could bear, using a medicine dropper not a syringe In the interval hot fomentations either wet or dry were applied to the auricle and mastoid One could imagine syringing at high pressure causing mastoid involvement the medicine dropper obviated this He treated an inflammatory process in this locality in exactly the same way as one in other parts of the body—namely by the application of heat, and the wet method seemed the only way to get heat to the *drum and possible to the middle ear* How long was the discharge to be allowed to persist With no marked improvement from treatment he advised opening and draining the antrum at the end of a fortnight and he had been well satisfied with the results The difficulty was to persuade the patient or his parents to allow operation, so many of their friends children had had discharging ears all their lives and seemed none the worse If there were adenoids he advised immediate removal and in most of the cases the discharge ceased without antrotomy

Dr RITCHIE RODGER (Hull) said that in discussing the treatment they seemed to be forgetting a most important item—in his opinion the most important 95 per cent at least of these cases were due to adenoids in the case of children, and to nasal obstruction in the case of adults In children he thought they must remove the adenoids if they were allowed to do so as the initial part of the treatment It was not a severe operation if the tonsils were left untouched In Class 1 he did the adenoid operation alone in Class 2 adenoids and paracentesis, and in Classes 3 and 4 adenoids and paracentesis if the perforation was not large enough or properly situated for effective drainage Even when there was discrete tenderness and oedema over the mastoid process these symptoms very frequently subsided after *removal of adenoids and* paracentesis

Mr DONALD WATSON (Bradford) mentioned those cases of mastoiditis without perforation of the drum In acute otitis media sometimes he incised the drum, sometimes he did not he was still uncertain which was the better method of treatment

RADIUM THERAPY IN CANCER OF THE OESOPHAGUS

THE RESULTS OF FIFTEEN YEARS' EXPERIENCE

BY

WILLIAM HILL, M.D., B.SC. LOND.,

Consulting Surgeon for Diseases of the Throat, Nose, and Ear, St. Mary's Hospital and Endoscopic Surgeon, Metropolitan Ear, Nose, and Throat Hospital

[Condensed Report.]

MALIGNANT strictures in the thoracic gullet may, for practical purposes, be regarded as absolutely outside the limits of radical surgery. They are rarely diagnosed in the early stages when the growth is of small extent and has not passed beyond the actual limits of the gullet, and, even when diagnosed by oesophagoscopic examination as thus limited, the *operation of lateral thoracotomy* is so fatal as not to be worth attempting. It is true that Torek of New York had a recovery from the immediate operation with survival for one year, but the fact remains that thoracotomic excision of a portion of the gullet is probably the most unpromising operation proposed in surgery from the point of view of death within a week or so of its performance.

We are usually reduced to palliative measures to give functional relief, either by enlarging the stricture lumen, or else by resorting to *gastrostomy* for the relief of impending starvation when endo-oesophageal measures fail. *X*-ray therapy and the injection of serums, animal extracts, and chemical substances—for example, metallic colloids—are usually disappointing.

The local means at our disposal for relieving the stricture are various, and include:

1. Dilatation of the narrowed lumen by the passage of bougies passed blindly or by immediate graduated bougieing carried out with the aid of the oesophagoscope.
2. By means of some form of intubation—for example, by Symonds's funnels or some modification of them (including Guisez's, Hill's, and Souttar's), or by long oro-oesophageal red rubber tubes, styletted or otherwise and inserted through the oesophagoscope.
3. Per-endoscopic removal of portions of protruding soft fungating growths by means of snares, of punch forceps or of rasps (Mosher and Bruning).
4. Superficial tissue destruction and reduction by galvano-cautery (ineffectual) or by surgical diathermy (Mollison).
5. Attempted diminution of the growth by endo-oesophageal surface applications of radium salts, or of radium emanation contained in metal cylinders which latter also act as screens to cut off the more violently destructive rays which cause almost immediate necrosis and which are dangerous in extent of action.

Radium radiation, like most therapeutic measures, is unfortunately uncertain in action. Some malignant formations are much more affected by radiation than others—sarcomas, for instance, speaking generally, being as a rule much more susceptible than carcinomas, and the softer forms of carcinoma more readily affected than the harder growths, hence fungating lesions generally yield much more efficiently than non-fungating. This does not mean, however, that hard, non-ulcerating squamous epitheliomas in the gullet never react well to radium rays, as occasionally they do, but the expectation is less promising.

As radium therapy of the gullet implies a long exposure and necessitates the retention of an uncomfortable, almost rigid radium apparatus for many hours, it follows that, in advanced cases, where the patient has been reduced to a low state of debility, radium therapy is contraindicated. An acute and sometimes fatal toxæmia may be set up, exceptionally in cases which do not appear to be far advanced and the general health only moderately lowered, by the liberation of massive doses of toxins into the blood stream, but this is much more likely to occur in advanced cases with an extensive and ulcerating lesion in the gullet. A *careful selection*, as far as it can be made, is therefore imperative.

A growth involving the gullet behind the trachea or the left bronchus is usually unsuitable for radiation if careful tracheo-bronchoscopic examination demonstrates that the growth has permeated the party wall and presents in the air passages, and if employed at all in this region it should be used with caution, in order to *avoid prematurely* bringing about a communication between the gullet and air passages. This happened in at least one of my cases, previously recorded, though the patient survived for nine weeks on account of the protection afforded by a Symonds funnel, which in this case effectually prevented liquid nourishment and swallowed secretions from entering the air passages. The diagnosis of perforation of the party wall is easy, as violent coughing and ejection of fluid ensues within a quarter of a minute of swallowing water.

It should be sufficiently obvious that it is a *sine qua non* in radium therapy of a malignant stricture to make fairly exact observations and measurements of the nature and extent of the lesion, especially longitudinally, and to *radiate the whole extent of the growth* as far as is practicable, superficially at all events. But let us suppose that an inexperienced individual orders a radium emanation apparatus from a radium institute, specifying a strength of emanation equivalent more or less to 100 mg. of radium bromide, and that he receives a styletted silver cylindrical container, the latter being, say, 1 mm. thick and 4 cm. long. Now it must not be assumed that the whole length of the cylinder, *or three-fourths, or even one-half* of it, is uniformly radio-active, if the styletted top of the cylinder is unscrewed and the contained capillary glass emanation tube removed, it may quite likely be found that the latter is approximately 1 cm. in length. If one application only of this apparatus is made for, say, fifteen or more hours to a malignant stricture 3 cm. or more in length, it stands to reason that only a moderate portion of the stricture is efficiently radiated—depending on the position in the cylinder of the active capillary tube. Failure to obtain any marked relief after such a procedure is only to be expected unless the active portion of the apparatus happens to be *vis-à-vis* the tightest portion of the stricture, when some moderate improvement might result. The whole length of the stricture must be radiated.

In my early hospital and private cases, and in many of my later private cases, I had the advantage of using Dr. Finzi's radium apparatus with a longitudinal radio-active efficiency of either 2·5 or 3 cm. With such an apparatus a stricture of about 1 inch long could be radiated by one application, whereas in strictures double or treble this length two or three applications must be immediately and successively made to successive lengths of the stricture if the lesion is to be anything like efficiently radiated.

In ordinary emanation therapy *for a stricture*, say, 3 cm. long the capillary emanation tube should be 3 cm. long, and it is most conveniently charged with the emanation equivalent of at least 150 mg. of radium bromide—that is, 50 mg. (approximately 25 millicuries) to each centimetre of length of the capillary tube. If the metal be silver and 1 mm. thick this amount of radio-activity forms a useful standard for an applicator, but the application can be tolerated and must be applied longer than if, for instance, *there is the emanation* equivalent of 100 to the centimetre.

Anyone embarking on radium therapy in the gullet must at least be prepared first to arm himself with information as to the character, breadth, and length of the stricture. A certain amount of useful information may be obtained by a study of the fluorescent screen phenomena observed during the swallowing of paste of barium or bismuth salts, which are *opaque to the Roentgen rays*, and also by the examination of an *x-ray print*, which should always be taken.

A skilfully-carried out endoscopic examination under general anæsthesia, however, gives the most accurate information which is attainable of the surface appearances, and allows fairly exact measurements *to be made* of the extent of the growth from above downwards. This examination is facilitated by the use of large tubes of 18 mm. diameter.

The question of dosage is most important and complicated, as several varying factors necessarily enter into consideration. Thus we have to take into account in using cylindrical applicators in the gullet:

1. The *radio-active dose* for each centimetre in length reckoned as the equivalent in milligrams of radium bromide (according to the British custom).
2. The *screen dose*, according to the thickness and density of the screen employed—for example, whether silver, platinum, lead or gold, a platinum screen, for instance, can be applied much longer than one of the same thickness of silver which is less dense. 1 mm. in thickness of the latter is employed by the Radium Institute.

[illegible] which [illegible] radioactive [illegible] with a screen of [illegible] tumour [illegible] to each [illegible]

The [illegible] in this country [illegible] weeks according to [illegible] but [illegible] radium [illegible]

So far back as 1909 I used an apparatus with a [illegible] slightly flexible silver stem attached to the proximal end of the cylindrical radium retainer. This stem protrudes from the mouth after the radium cylinder has been accurately adjusted to the diseased portion in the tractured area and the stem is then bent sharply to form an acute bend at the angle of the mouth, and is then curved to the surface of the cheek or even moulded and buried by extra trapping. Previously, for the comfort of the patient the stem is likewise bent behind the fauces so forming a pharyngeal angle, great care being taken in adjusting this not to draw the cylinder up out of its place in the stricture.

In February, 1911, I reported in detail to the Medical Society of London two more cases of malignant stricture of the gullet treated by radium therapy. In three patients there was total temporary local disappearance of naked-eye evidence of growth.

In each of the three patients a total [illegible] radium applications were made in the course of the year, during which time the part on 2 st. in weight and remained free from any subsequent [illegible] growth for a further period of 10 months in one of the cases, the last application [illegible] negative finding was made in the gullet on January 4th, 1912, to which month [illegible] the disease was obviously suffering from secondary growths in the liver and abdominal glands. The primary tumour, if not microscopically [illegible] was greatly [illegible] and a cavity of the growth was [illegible] no [illegible] period than five years and [illegible] to two [illegible] radium treatment [illegible] of the accompanying with [illegible] tumour [illegible] following radium [illegible] occasional gradual [illegible] ing.

The next best case which I report [illegible] that of a man whose malignant growth had apparently [illegible] one application only of Dr. Knaggs's radium, the patient [illegible] in weight in two months and his swallowing [illegible] normal. It was with difficulty he was persuaded to submit to a fourth prophylactic application for months after the third. He was so well that he failed to present himself at hospital until the [illegible] year and one month after the first application of radium. He then complained of a slight amount of recurring dysphagia, although he was then 3 stone heavier than when first treated. There was evidence of some recrudescence of growth even with the oesophagoscope, it being a little of a soft fungating character and [illegible] readily when touched with the end of the endoscope. He was again radiated, but did a few months later from invasion of the lung [illegible] to frequent haemorrhage. He walked remarkably well until a week to the end, but was rapidly losing flesh.

Another man reported on in 1911 as having from [illegible] experience of growth when endoscopic examination had revealed prolonged radium applications at intervals during twenty months the [illegible] malignant stricture extending nearly the whole length of the supraclavicular portion of the gullet. The applicators in this case could be made and were made both externally and internally in the region. He put on 2 st. in weight and remained free from [illegible] evidence of growth in the gullet for three months at least. He lived for two years and nine months after the first application of radium, wallowing nearly normally, to the end, death was due to a sudden profuse haemorrhage, though whether this originated in the primary lesion in the gullet or from a secondary one in the air passage was not determined as the patient died suddenly at home in the suburbs and there was no *post mortem* examination.

Of my 21 cases reported in February 1911 there was temporary gross local disappearance in no less than 5 cases, there was remarkable improvement both objective and subjective in 7 cases, substantial temporary improvement in 7 other cases and no improvement whatever in 4 cases.

I have now dealt altogether with seventy-seven cases of malignant stricture in the gullet by radium. Not all of the later cases were so carefully selected as those in the first series already reported, as in some instances the patient and his medical attendant urged that radium should be used on the off chance after appreciating the caution that improvement was very problematical and the risk by no means negligible.

The number of applications varied in individual cases from one to eight. Two-thirds of the cases had more than one application. I have alluded above to three cases in my first published series (which overlapped in time into the second series) in which there was apparent gross disappearance of growth for from two to no less than five years. I have had at least four further cases in which there was apparently a temporary local disappearance of recrudescence of growth when the diseased area was visually examined with the aid of the oesophagoscope. The temporary freedom from recrudescence of growth lasted in the four cases for from six to eighteen months.

To sum up my results of radium therapy: in about one-third of the cases there was remarkable improvement in another third there was very substantial improvement and in the remaining third the improvement was either very slight and [illegible] there was either no improvement at all or the patient was rather worse than before. In three cases the measure was followed by fatal results within a few days of the application.

I have only included in my cases malignant growths which were obviously primary in the gullet, exception to the gullet from the deep pharynx from the thyroid gland from the mediastinum and from the stomach have been deliberately excluded.

SOME OSSEOUS GROWTHS OF THE NASAL AND ADJACENT BONES

BY

W. H. KELSON, M.D., F.R.C.S.

Surgeon to the Hospital for Diseases of the Throat, Golden Square.

[*Abstract.*]

The first condition dealt with was leontiasis ossea. Virchow originally applied this title "leontiasis" to certain bony growths which he erroneously considered were analogous to elephantiasis of the extremities. The disease had been considered to be a variety of osteitis deformans and also of acromegaly, but differed from the former in affecting the face, and from the latter in having apparently no connexion with the pituitary region. Leontiasis ossea generally began in youth and gradually. It appeared to be due to some kind of inflammatory process, but no microbe cause had yet been established. Its actual point of origin appeared to be in some part of the nasal cavity. Professor Knaggs had divided the disease into two varieties. In the first it took the form of a slowly spreading periostosis, and in the second of a profuse osteitis. In the periosteal form the disease appeared to be unilateral in origin, the nasal cavities might gradually become filled with bone masses, both septum and turbinates being affected. Nasal obstruction was generally one of the earliest signs. In the second variety—namely, profuse osteitis of the bones of the face and skull—there was no periosteal bone deposit, but the bones became generally swollen as though they were inflamed, and on section was found to be reddish, softer and more vascular than normal, with occasional hard patches of dense bone. The skull bones were often enormously thickened, old bone being replaced by new. Sometimes the osteitis was not diffuse, but limited to one or two bones, especially the frontal bone or one of the jaws. In many of these cases there was also dental caries—a condition associated with osteitis fibrosa by Professor Knaggs. Mr. Kelson gave details of a few cases in which the condition of the nasal cavity had been specially mentioned. In the first case reported in the BRITISH MEDICAL JOURNAL in 1889 by Young, of Bristol, the patient developed painless and symmetrical bony bosses on the superior maxillae at the age of 39; there was no family history of this affection. Two years afterwards mental changes necessitated confinement in an asylum; later the sense of smell disappeared, the vision became weak, and exophthalmos and ectropion appeared. The patient died seven years after the appearance of the first signs. The nasal cavities were filled with bony masses, the frontal sinus and maxillary antra were occluded by bone, and the orbital cavities reduced in size, the bone being cancellous in structure. The sella turcica was normal, and the pituitary body unaffected. In 1903 Mr. Kelson had shown a case at the Royal Society of Medicine; this patient, a man, had for eight years noticed bony swellings in the region of the nasal processes of the superior maxillae with increasing difficulty in nasal breathing. The nasal fossae were blocked by enormously enlarged inferior turbinals; the septum was unaffected, but there were also bony bosses on the mandible, maxillae, and frontal

bones There was no pain, nor evidence of syphilis, and no carious teeth were present The nasal airway was cleared by operation, and the patient was subsequently kept under observation for two and a half years without any recurrence or increase in size of the bony bosses In five out of eight cases described by Westmacott, at the International Congress of Medicine in 1913, carious teeth were found present, but their extraction did not cure the disease The condition was unilateral, and the orbital and nasal cavities were not affected, the alveolar process was chiefly concerned, the antrum being largely invaded In one case sarcomatous elements appeared to be present, but in no case did recurrence follow an operation Westmacott did not regard these cases as leontiasis ossea, but believed them to be cases of osteitis fibrosa Douglas Guthrie described two cases in 1923 the first was a smooth boneless swelling of the left upper jaw, in a girl of 16 In the second case the swelling of the upper jaw, in a child of 4, had been present since birth Many points of resemblance existed in these various cases A history of syphilis was rarely obtained, tuberculosis and malignancy were out of court, and staphylococcal or streptococcal inflammation seemed unlikely Possibly some other bacterial infection or toxin was responsible, and Mr Kelson urged practitioners to be on the lookout for early stages of such conditions in order to clear up the mystery concerning them He then referred to bony growths in the upper part of the maxillae occurring in negroes, described by various authors, and concluded with the consideration of the genuine ivory-like osteomata occurring in the frontal sinus and orbit

This paper will be published in the *Journal of Laryngology and Otology*

The PRESIDENT expressed his indebtedness to Mr Kelson for a paper dealing with a group of cases which had not received adequate attention from the standpoint of pathogenesis As far back as 1899, when the sixth International Otological Congress met in London, all the known specimens of these osseous growths in the museums of the London hospitals were loaned to the Congress The descriptive catalogue[1] of the Congress Museum afforded a useful record of the subject at that time For obvious reasons it was difficult to obtain specimens showing the symmetry of some of these facial growths, but such a specimen was loaned by St Thomas's Hospital

Memoranda:
MEDICAL, SURGICAL, OBSTETRICAL.

TWO OBSTETRICAL EMERGENCIES

THE following account of two cases recently treated at the Dufferin Hospital, Calcutta, seems of sufficient interest to merit publication

CASE I

In March, 1923, an achondroplastic dwarf, aged 19 with a markedly contracted pelvis, was admitted in labour at full term Labour had commenced the day before admission, and she had had a great deal of inexpert examination and manipulation in her home The bladder and intestines were very distended, the membranes had ruptured, and an offensive discharge was coming from the vagina As delivery was practically impossible, even by craniotomy, it was decided to perform Caesarean section A stillborn male child was removed by the abdominal route, followed by a very unhealthy placenta and ragged membranes The interior of the uterus appeared so unhealthy that it was swabbed with iodine before being sutured this was done with a buried muscular layer of silk sutures, and the superficial peritoneal layer and the abdominal wound were closed in layers in the usual way Recovery was uneventful

Between fifteen and sixteen months later she was again brought to hospital in labour and at full term labour had commenced the day before admission, though she had been warned to report at the beginning of the ninth month if she again became pregnant She was rather collapsed, the lips and mucous membranes were blanched, and she was perspiring freely though she showed no untoward restlessness She complained of abdominal pain especially when lying on her back and on any attempt at palpation Vaginal examination showed that the cervix was dilated to admit two fingers, though no definite presenting part could be determined The membranes were unruptured, and it was decided to perform Caesarean section at once When the abdomen was opened and a few adhesions of omentum to the abdominal scar had been broken down I saw what appeared to be a thin walled cyst, this was the child inside the intact membranes with the placenta free in the abdominal cavity This was removed, and the uterus was found to have ruptured in the line of the old scar and to have contracted down after having completely extruded its contents Some large blood clots in the abdomen were removed The child, a male, was stillborn A pint of subcutaneous saline and of strychnine 1/60 grain were injected during the operation The ruptured edges of the uterus were freshened and resutured, and the abdomen closed in layers, about half a pint of saline solution being left in the peritoneal cavity The patient's recovery was uneventful

The question arising was whether the rupture was due to pregnancy distending the uterus again so shortly after the first Caesarean section and while the scar was comparatively soft, or whether the sepsis present in the first confinement was a contributory cause Moreover, was I justified, in the circumstances, in leaving her unsterilized, to risk the possibility of a repetition of these events should pregnancy occur again? I think I was right in so doing, since live children count so largely in the life of an Indian woman, and these two experiences have not daunted the patient, who still hopes to have a live child

CASE II

The history of this patient, a Hindu lady of high caste, was as follows

Eight years previously she had been delivered of a stillborn female child by an Indian dhai The afterbirth had given trouble, and the dhai had removed it manually, causing great shock and pain to the patient Since that time the patient had had no children and came to me to inquire if there was any reason for this On examining her I found that she had an inversion of the uterus which had probably existed since the first delivery I gave a guarded prognosis, but promised to try to replace the uterus For this purpose I took her into a private cottage in the hospital and treated her with four hourly saline douches and applications of ichthyol to the inverted uterus, her bed being raised at the foot After four days of this treatment I made the attempt of replacement under an anaesthetic I fixed the anterior lips of the cervix with a tenaculum in my right hand and with my left hand in the vagina digitally compressed the uterus at the fundus, at the same time gently pushing it up through the cervix till half had gone up When it seemed that I could do no more, my hand being almost paralysed, the fundus slipped up suddenly with a sucking noise—the replacement was complete, and the cervix contracted down

In all, the operation took from twenty minutes to half an hour No one was more surprised than I myself at the result, for I only undertook to try the replacement in order to satisfy the patient and her relatives The after treatment consisted of douches and keeping the patient in bed with the foot of the bed raised, till the tenth day Examination before she left hospital showed the uterus apparently normal in size and position the fundus was palpable on bimanual examination where previously there had been no mass felt and the bimanual impulse was normal I have not yet heard whether she has since become pregnant

Superintendent Dufferin Hospital,
Calcutta

A CASE OF HYDATIDIFORM MOLE

THE rarity of occurrence of hydatidiform mole renders the following details of such a case worthy of publication

Two years ago I was called to a woman, aged 28, about five months pregnant, and apparently suffering from a threatened miscarriage I administered an antispasmodic and gave the usual advice, believing that it was a false alarm The next morning the labour pains increased, and the os uteri increased to the size of half a crown, her temperature was 100° F

I left the patient in charge of a nurse Later that day the labour pains became much more violent and closer together, I found the os largely dilated with a mass protruding from it

With due precautions I removed this egg shaped cystic tumour It was followed in quick succession by a large number of similar cystic tumours, varying in size from a pin's head to a large hen's egg I managed to curette the uterus with the fingers, and removed altogether slightly more than a gallon of these cysts There was no sign whatever of a foetus The chorion had evidently become absorbed into the roots of this bunch of "grapes" Some of the cystic moles near the os uteri had already undergone partial degeneration, this process probably gave rise to some septic absorption which accounted for the fever The next day, as the patient's temperature had risen to 101·5°, I sent her to an infirmary where, under an anaesthetic, the uterus was explored, and it was stated that "small pieces of membrane and placenta were removed by the fingers only" She quickly recovered and was discharged within a fortnight It is interesting to note that this woman is again four months pregnant

In the literature I have found mention of seventy-five cases of this kind, and one author states that the proportion of occurrence is only about one in a million pregnancies

COLLOIDAL COPPER TREATMENT OF CANCER

At a meeting of the Cardiff Medical Society on November 11th, the President, Dr I I Brierley gave an address on the cancer problem

Dr Brierley first surveyed the history of cancer, which, though known to Hippocrates and Celsus and even earlier, was not seriously studied until about 1870, when Virchow appeared as the pioneer of cancer research Collective cancer research started in this country with the reorganization of the cancer department of the Middlesex Hospital in the beginning of this century and the foundation of the Imperial Cancer Research Fund in 1902 Statistics showed that cancer mortality had trebled during the last sixty years and that the true incidence was now later than formerly New Zealand in 1899, had shown that the average death rate from cancer then was 47 per 1 000 and that the highest mortality rate was 156 per 1 000 in chimneysweeps The experimental production of cancer in animals by irritants or by the cancer in rat by feeding them on cockroaches infected by the larvæ of a nematode *Spiroptera obvelata* (Johannes Ehlinger of Copenhagen) the transplantation of cancers in animals and the continuous propagation of mouse cancer through a series of mice were mentioned A brief description was given of the histopathology of cancer As regard prophylaxis the patient advocated the removal of all possible causes of irritation and advised that the excessive use of meat and alcohol should be avoided being possible causes He reviewed the various treatments and "cures" from the early ages down to the present time and in touching upon the surgical treatment referred to the paper by Sir Harold Stiles of Edinburgh entitled "Dissemination of cancer of the breast and the necessity for" treatment by extensive operation (BRITISH MEDICAL JOURNAL, 1899 vol i p 1452) in which he laid great stress upon the extensive lymphatic system of the breast and the necessity for the removal of all the tissues beneath the breast and in the axilla containing the lymphatics pointing out that secondary operations were never so satisfactory as extensive primary operations

Dr Brierley then referred to the memorandum issued by the Ministry of Health, reported in our issue of May 24th (p 924), in which are summarized deductions from the investigation of the records of upwards of 20 000 cases of cancer of the breast by Dr Janet Lane Claypon In the light of present knowledge surgical operation offered the best chance of cure for cancer, but after his own experience with colloidal copper he was not prepared to admit that it was the "one chance" stated in the memorandum He believed that many patients would have had a better chance of survival over the periods mentioned in the memorandum if a course of colloidal copper injections had been given after operative treatment He reviewed the treatment by means of x rays and radium, and then returned to the treatment by colloidal copper and selenium, giving notes on cases treated by him

Two cases of nodular growths in the breast with secondary gland in the axilla in which leave for operation had been refused were treated by him with intramuscular injections of colloidal copper the growths and the glands disappeared after a course of injections extending a little over a year Both patients were still alive and well ten and seven years after the commencement of the treatment

A patient with a large scirrhous carcinoma of the breast had her breast removed and the axilla cleared in November 1916 the supraclavicular glands on the same side were found to be enlarged in February 1918 Intramuscular injections of colloidal copper were given over a period of eight months the glands disappeared and the patient was still in good health

In a patient aged 62 with a history of haemorrhagic vaginal discharge over a period of two years vaginal examination demonstrated the clinical signs of cancer of the cervix Leave for operation was refused but consent was given for intramuscular injections of colloidal copper after even injection the haemorrhage and discharge had ceased and the patient refused further injections The cervix was then found to be healed and smooth The patient died away from home nine months later from a stroke no return of the vaginal discharge having occurred

A patient who had her breast removed and the axilla cleared for medullary cancer in August 1919 received a course of colloidal copper injections over a period of three months She had had no recurrence and was quite well

Another patient had the right breast removed and the axilla cleared for medullary cancer in February 1920 A there was a small nodular lump in the left breast with enlarged glands in the axilla and the patient did not wish to have a second operation a course of colloidal copper injections was given over a period of three months the nodular lump and glands disappeared In September 1923 the patient returned on account of some enlarged glands in the right supraclavicular region after a course of colloidal copper injections lasting four months the glands subsided The patient was alive at the present time was in excellent health and no glands could be felt

Two patients with advanced and inoperable carcinoma of the rectum had been treated by him one improved and put on weight but died in twelve months the other received no benefit

A case of inoperable cancer of the rectum treated by colloidal copper and selenium had been reported by Mr Lionel E C Norbury FRCS in the *Proceedings of the Royal Society of Medicine* June 1923 After treatment for over two years no growth or ulceration could be detected and the general health of the patient was excellent

In conclusion Dr Brierley urged the trial of colloidal copper after operation for cancer and in inoperable cases He emphasized the importance of not being discouraged if there was no immediate improvement from the treatment and of persevering with the injections until the patient was cured or refused further treatment or until the condition of the patient had become hopeless

SURGERY OF THE BILIARY PASSAGES

At a meeting of the Medico-Chirurgical Society of Edinburgh on December 3rd the President Sir DAVID WALLACE in the chair Professor D P D WILKIE read a paper entitled "Observations on the surgery of the biliary passages"

Professor Wilkie referred to the divergent opinions as to the place of surgery in the treatment of biliary disease though the frequency of biliary infection and gall stones was generally admitted symptomatology and diagnosis were not discussed with the exception of a reminder that flatulent dyspepsia in stout multiparous females very frequently indicated cholecystitis and usually gall stones Neglected biliary disease was a fruitful source of pronounced ill health and at times led to death from pancreatitis and malignant disease The chronic dyspeptic symptoms had a most deleterious effect on the health of the patient Palliative treatment might obviate later surgical treatment Professor Wilkie divided his cases into three groups (1) Cases of biliary trouble demanding surgical treatment (2) cases unsuitable for operation (3) cases in which surgical treatment was debatable In Group (1) he included all cases of acute obstructive cholecystitis in which there was an inflamed and distended gall bladder, cases of flatulent dyspepsia punctuated by occasional attacks of biliary colic and local tenderness and cases of recurrent cholangitis with loss of weight rigors and intermittent jaundice Group (2) included patients suffering from other organic diseases such as bronchitis myocarditis and malignant disease Group (3) included the dyspeptic stout female with symptoms suggesting one aseptic cholesterin stone Professor Wilkie favoured early operation because many of these cases finally became worse and required an operation The group included also vigorous patients with mild attacks of cholecystitis and probably a primary tooth focus of infection and thirdly the deeply jaundiced patient He further classified his cases into five groups from the operative point of view In the first group cases urgently requiring operation there were 8 males and 21 females and the cholecystitis was almost always of the acute obstructive variety In 3 cholecystectomy and in 16 cholecystostomy was performed there was one death a subacute pancreatitis being present The tentative conclusion drawn from this small group was that cholecystectomy was the ideal treatment if the local and general condition was not adverse In the second group interval operations on the gall bladder there were 27 males and 76 female In 99 per cent a history suggesting gall-bladder trouble was obtained of two to thirty years duration In all cases some degree of cholecystitis was present and gall stones were found in 79 cases Cholecystectomy was performed in 47 cases and cholecystostomy in 50 The reasons for adopting one or other method were discussed the functional capacity of the gall bladder wall being the main deciding factor In this series there were four deaths in one case the general condition of the patient

was poor, in two general septicæmia was present, the gall-bladder infection being incidental, and in the fourth case there was marked cirrhosis of the liver Professor Wilkie's general conclusions on this series were that cholecystectomy *should be performed if* the gall-bladder wall was grossly diseased, but if the wall was relatively healthy and all stones were removed recurrence was unlikely In the third group, disease of the common bile duct, there were 5 males and 27 females Many of the patients were in a very poor condition, and in 28 cases one or more stones were found—in most only one stone The operation included free exposure of the common duct, puncture with the hypodermic needle, removal of calculi, and securing the patency of the duodenal opening Some weakly patients were fed for a few days through a catheter passed into the duodenum through the duct Four deaths occurred, one owing to haemorrhage from a large duodenal ulcer, another from acute pulmonary oedema another from haemorrhage into the pancreas due to a wound in the duct, and the fourth after a large piece of gut had been removed because of tuberculous strictures The lessons from this series were the value of free exposure in all biliary operations, aspiration of bile and feeding by a duodenal tube In the fourth group malignant cases, there were 10 cases of carcinoma of the head of the pancreas, 2 cases of primary cancer of the common bile duct, and 6 of the gall bladder Professor Wilkie was convinced that gall stones predisposed to carcinoma In the 6 cases of gall-bladder carcinoma there were long-standing histories of biliary trouble, and gall stones were present In the fifth group, cases with acute or subacute pancreatitis, most of the patients were over 60 years of age, showing the final phase of a chronic and neglected malady All were operated on for urgent symptoms

Professor Wilkie also discussed the question of operation in the presence of jaundice In the whole series of 197 this symptom was present in 35 patients at the time of operation The danger of liver inadequacy was combated by giving glucose before and after operation, but the tendency to haemorrhage in the malignant cases was a serious problem The injection of 30 c.cm. of 30 per cent. sodium citrate was practised, and he had no hesitation in advising this line of treatment and continuing it after operation The age factor in biliary surgery was touched upon, also the matter of associated lesions operated on—for example, diseased appendices The following conclusions were drawn

(1) In action of the gall bladder and gall stones must be regarded seriously in view of the dangerous complications which might eventually supervene (2) Operation in the early and uncomplicated stages was attended with little risk (3) Cholecystectomy was the operation of choice when the gall bladder was seriously diseased (4) Cholecystostomy was effective where the gall bladder had retained its elasticity, and was capable of further function (5) Free exposure of the common duct should be secured in all cases (6) Operation on deeply jaundiced patients with malignant disease was attended with considerable immediate risk (7) Pre- and post-operative treatment to minimize haemorrhage and hepatic shock were essential for all deeply jaundiced patients (8) Operation in the late stages, when acute or subacute pancreatitis had developed was attended with grave risk numerous complications and considerable post-operative morbidity (9) The time for surgery was before and not after complications had set in

Immunity to the Pneumococcus

Dr. STANLEY DAVIDSON referred to the fact that anti-pneumococcal serum was used so far back as 1881, but had little therapeutic effect till the work of the Rockefeller Institute in 1917 explained its failure and defined the different types of pneumococci by agglutination experiments It was also found that potent protective serums could only be obtained from Type I pneumococcus Reference was also made to the incidence of pneumococcal types in lobar pneumonia, and the reduction of mortality in lobar pneumonia at the Rockefeller Institute by using intravenous serum in large quantities The advantages and disadvantages to the general practitioner of serum treatment were summarized the latter being (1) cost of serum, (2) technical difficulties of administration, (3) production of serum sickness (4) necessity of co-operation with a trained bacteriologist The results of 44 cases of pneumococcal infection were described, and it was shown that Type I was the most prevalent organism, 17 empyema cases being all due to this type Dr. Davidson then discussed the experimental side of the question He used three kinds of vaccines to produce active immunization—namely, (1) the ordinary heat-killed saline emulsion, (2) the so-called detoxicated vaccine, and (3) defatted vaccine In a paper read at the Annual Meeting of the British Medical Association in July, 1924 (reported in our issue of December 13th, p. 1103), the speaker had shown that detoxicated and defatted vaccines were not equivalent to the saline heat-killed vaccines in the production of antibody, in these experiments *B. suipestifer* had been used The question of relationship between antibodies and immunity with reference to protection from a lethal dose was raised With the exception of the antitoxins it had to be admitted that they were unable to state definitely the relationship of antibodies to immunity The production of antibodies might, however, be regarded as an indication of the antigenic value of a serum The real test of a vaccine was, therefore, the production of immunity to a lethal dose of the organism Dr. Davidson then described a new series of experiments in which the pneumococcus was used The three types of vaccine were again employed Serums from rabbits injected with these vaccines were introduced into mice and varying strengths of vaccines employed The results were shown by a full table of figures indicating the final conclusion These results demonstrated that (1) the serum from animals injected with ordinary vaccines and the Rockefeller immune serum give complete protection against 10,000 lethal doses of pneumococci, (2) serums from animals injected with detoxicated and defatted vaccines showed no protective properties, since normal rabbit's serum gave similar negative results, (3) in a protective experiment of this kind control animals should receive serum *plus* culture, since introducing foreign protein produced a temporary lowering of resistance Further experiments to show the effect on rabbits treated with vaccines and then injected with live organisms demonstrated that the animals injected with the saline vaccine survived does that killed the animals treated with defatted and detoxicated vaccines The condition of the rabbits at the end of the immunization experiments differed greatly Those injected with detoxicated vaccines were in good health seven days after the last dose, those treated with defatted antigens were in fair health, and hard lumps could be felt at the site of injection, those treated with ordinary vaccine had wasted to some extent, and those treated with a live culture were very ill indeed Therefore the animals in relatively good health showed the least resistance, and those with toxic symptoms were proved by experiment to have a serum of high protective value Finally, Dr. Davidson summed up by saying "As judged by production of antibodies and protection to lethal doses of micro-organisms, detoxicated and defatted vaccines have no immunological value comparable to that of ordinary heat-killed bacterial vaccines"

STRUCTURE AND FUNCTION OF THE CORPUS LUTEUM

A MEETING of the Section of Obstetrics of the Royal Academy of Medicine in Ireland was held on November 28th, the President, Dr. L. CASSIDY, in the chair

Dr. BETHEL SOLOMONS read an abstract of a paper written by him and Professor Gatenby on the formation, structure, and physiology of the corpus luteum of man, the pig, and the duck-billed platypus The theories relating to its formation were discussed, and it was stated that the investigations made indicated that the membrana granulosa layer was the responsible factor in formation The authors had found that liquor folliculi, given by mouth to human patients, had no effect upon the haemorrhages of puberty, adult life, or the climacteric On rats, however, it had a great effect, these experiments were similar to those of Allen and Doisy, but the rats were fed instead of being injected Generally speaking, ovariotomized rats were affected sexually Corpus luteum extract, given by the mouth, was found useful in the treatment of scanty and absent menstruation, it was valuable in the treatment of sterility, but of little service for menorrhagia and metrorrhagia It was occasionally helpful in treating

dysmenorrhœa, but menopausal symptoms were seldom relieved, it was also successful in some cases of vomiting of pregnancy When administered hypodermically it had cured some cases of severe vomiting and menstrual epilepsy It was difficult to understand why corpus luteum administered by the mouth or hypodermically should cure menorrhœa considering its physiological action, this point required intensive investigation by the physiologist in combination with the gynæcologist Theoretical explanations were that the drug stimulated the ovary to action or that the corpus luteum after administration acted in the same manner as the true corpus luteum It was difficult to understand why corpus luteum given throughout pregnancy should help to prevent the stillbirths which usually occurred in the last two months Possibly it produced a healthy corpus luteum which supplied the hormone necessary to the child from the seventh month onwards

Professor J Bronte Gatenby showed lantern slides illustrating the formation of the corpus luteum The theca interna elements preserved their integrity until regression of the corpus luteum set in so that the corpus luteum cells were really of single origin from the membrana granulosa The corpus luteum of pregnancy was not always larger than that of menstruation and the presence or absence of fatty substances constituted no sort of index as to the existence of pregnancy

Professor H Pringle did not agree that the luteal cells originated only from the granulosa cells He believed that the granulosa and interstitial cells originated from the luteal cells If they had two separate origins two specific hormones would be expected There were three separate hormones (1) the hormone of the interstitial tissue, (2) the hormone of the Graafian follicle and (3) the hormone of the corpus luteum, and this hormone seemed to antagonize the second hormone The observations of Dr Solomons and Professor Gatenby seemed to be incompatible with this hypothesis One of the most interesting features of the effect of corpus luteum on ovulation was seen in cases where ovulation only followed coition After sterile coition in a rabbit the corpus luteum was almost indistinguishable from the corpus luteum following pregnancy, and the corpus luteum persisted nearly as long as if the corpus luteum ovum had been implanted When the abdomen was opened and the surface of the ovary was follicized a factor was introduced which might be in every way compatible with sterile coition The whole question was still in a very unsatisfactory state, although Professor Gatenby had added enormously to their knowledge of the physiological changes which occurred in the corpus luteum

Professor J M O'Connor had been very interested by the hormone therapy referred to that evening some of the results given could not be ascribed to physiological effects He had noted particularly the statement that there was no interstitial tissue present in the ovary since he had previously been led to believe that interstitial tissue was the most important thing present in the ovary

Dr W Fearon said that the bodies of the hormones were simple molecule derived from well known amino-acids which was why it was so important that these acids should be in the body to augment the internal secretion For some internal secretions, such as insulin no formula had yet been obtained

FREQUENCY OF MICTURITION IN WOMEN

At a meeting of the London Association of the Medical Women's Federation held on December 9th the President Miss M Chadburn, in the chair Miss F C Lewis read a paper on frequency of micturition in women

Miss Lewis approached the consideration of this symptom from the standpoint of its etiology and clinical characteristic, and discussed its differential diagnosis The causes of this condition could be stated as (1) disease of the bladder (2) irritation of an otherwise healthy bladder, (3) incompatibility between the bladder and its contents, (4) a group of nervous diseases organic and functional, (5) diseases of the kidneys and ureters In the first group cystitis was extremely common in women and might follow any change in the bladder which lowered its resistance Prolonged congestion, retention of urine, traumatism, and changes in the bladder wall predisposed to cystitis, these might be masked by a secondary inflammation but in every case of cystitis the original lesion should be looked for and treated Frequency of micturition in cystitis was easily explicable, but it was less easy to account for it in other bladder lesions such as an uninfected diverticulum A simple papilloma did not cause frequency except when bleeding profusely, and then apparently because of sudden increase in the contents of the bladder, since blood was not irritating to the bladder Miss Lewis had seen cases in which blood was coming down from one of the kidneys in considerable amount, but the bladder itself was normal and there was no frequency Malignant growths, stones or foreign bodies always tended to cause frequency Irritation of the bladder leading to frequency might be caused by external pressure —for instance by an enlarged uterus or an ovarian cyst A uterus of normal size, if much anteflexed or lying horizontally across the pelvis might impede the filling of the bladder and cause frequency This was sometimes accompanied by pain relieved by micturition, unlike the pain associated with disease of the bladder Urethral conditions such as external prolapse of the urethral mucosa which occurred typically at the extremes of life might cause frequency so also might a urethrocele when the patient complained of repeated calls to empty the bladder, and a few drops of urine escaped when she coughed or made any sudden effort Acute pelvic inflammations had probably an irritating effect on the bladder, while in cases of chronic cervicitis a trigonitis could generally be detected by cystoscopy Irritation from within might be caused by change in the reaction of the urine bacilluria, or an abnormal amount of phosphates or oxalates

Relative inadequacy of the bladder to its contents might be due to the bladder being contracted owing to inflammation or to polyuria Nervous diseases might cause motor symptoms of the bladder hyperexcitability or hyperæsthesia frequency usually occurred in both cases Hysterical and neurasthenic polyuria might also be met with In the last group, frequency due to renal and ureteric conditions, inflammatory and several other lesions were included, the more common causes were, however those of the previous group With regard to diagnosis it was important to ascertain the number of times the patient passed water by day and by night and whether the frequency was continuous or sporadic The quantity of urine passed each time indicated whether the bladder was inadequate or whether there was polyuria Urgency with frequency was said to occur in some of the spinal cord lesions and incontinence in some of the urethral conditions In cases of painless frequency without other symptoms some cause outside the bladder should be suspected The routine clinical examination established the presence or absence of caruncle, prolapsed urethra or urethrocele Polyuria might indicate some surgical disease of the kidneys such as chronic relapsing pyelitis or pyelonephritis or in young people early tuberculosis Frequency accompanied by pain or by some abnormality of the urine nearly always indicated a lesion of the urinary tract and in locating this the situation and character of the pain and its timing in relation to micturition were important

Dr Irene Yates dealt with the clinical aspect of those diseases in which frequency was a symptom The commonest of these were (1) disorders of the nervous system (2) inflammatory conditions of the urinary tract (3) chronic interstitial nephritis (4) diabetes mellitus The latter commonly met with were diabetes insipidus and the so-called diabetes phosphaturia and oxaluria Dr Yates discussed frequency of micturition as a symptom of diabetes mellitus and of diabetes insipidus In diabetes insipidus polyuria might be due to a tumour of the pituitary or to irritation of the gland from without as in syphilitic meningitis In other cases the polyuria seemed to depend on a polydipsia of nervous origin here the volume of fluid excreted was no more than the intake whereas in the former cases it exceeded it

Dr C Peake the President Mr R Coltson Holmes Dr L M Jeffries Dr M A Blair Dr M Dobie, Miss Bannerman Dr I M Guest Dr M Brady and Dr Justina Wilson also spoke

Reviews.

AMERICA IN THE WAR

Anthropology

THE first part of the fifteenth volume of the history of *The Medical Department of the United States Army in the World War*[1] relates exclusively to army anthropology. A sidelight will be thrown on the character of its contents if it be mentioned that its index occupies about 60 pages and must supply at least 4,000 references, in addition to some 1,600 others in the table of contents. These calculations will suffice, perhaps, to suggest the tendency of mind which by a species of infection is liable to be created by even an incomplete study of the volume. It may be mentioned that besides letterpress it contains at least 400 elaborate statistical tables, plates, and graphs. It is, in short, by no means a book to recommend for perusal by way of whiling away an after-luncheon odd half-hour, but one which even a serious student may well find difficult to digest unless he takes off his coat for the task. Should he do so he will find himself rewarded by a good deal of information of an interesting and more or less directly useful kind.

On the whole, however, the volume will no doubt appeal chiefly to the professional anthropologist, who, if he lives on this side of the Atlantic, would probably shorten his study of it by refusing to take any notice of a good deal of the text and a great many of the tables. His action would be justified by the fact that the material thus rejected is of essential interest only to inhabitants of the United States, since it relates to the statistical distribution of the basic figures amongst its territorial components.

The volume is almost purely statistical, so, since statistics have been said to be capable of being made to prove anything, it is fun to point out that those responsible for the preparation of the volume do not appear to have directed the work with any preliminary prejudices. They have been content to get together as many data as they could, and then analyse and correlate them in a number of different ways. The primary object would seem to have been first to compare such coloured components of the population of the United States as came under observation with the components of European origin, and then to compare among themselves the eight European nationalities which chiefly contribute to the population as a whole.

One point of general interest that emerges is the immense fund of man strength that the United States possessed when it entered the war. Within about twelve months after that date there were registered as being between the ages of 18 and 45 over 23 million men, and of these nearly 11 million were of ideal military age—that is to say, between 21 and 30. There is no indication of how many of these men were ever medically examined for recruiting purposes, and there is initially a certain amount of obscurity in regard to the exact number of individuals from whom were derived the data handled in the volume. Comparison of the tables and the text leaves, however, no doubt that the number of individuals anthropometrically considered was 2 million, that 500,000 of these were also considered from an essentially medical point of view, and that, in addition, 100,000 individuals who may or may not have formed part of the stated 2 million were considered from the point of view of general anthropology.

The men forming this 2-million group were those first passed for service by recruiting boards, and the measurements derived from them were those ordinarily taken on such occasions—namely, stature, weight, and chest measurement. The half-million group was made up of individuals discharged on medical grounds when the 2 million men already in mobilization and training camps were again subjected to examination. The smallest group mentioned consisted of "veterans"—that is to say, it was made up of individuals who, whether they had been employed overseas or otherwise had all served as soldiers for at least several months. Their measurements were taken at the time of their demobilization, under the supervision of expert anthropologists by men specially trained for the purpose.

The ostensible object of this examination was to secure data for the building of manikins for the use of army tailors of the future; but since it was undertaken at the request of the Medical Department, and carried out by it, the stated object was probably not the only one in view. The measurements taken were stature, span, sitting height, and height of the knee-joint, sternal notch, and pubis, the breadth of the shoulders and pelvis, the breadth, antero-posterior depth, and circumference of the chest, the distance from the second dorsal vertebra to the styloid process of the right ulna, the circumference of the neck, of the waist, and of the thigh, of the leg just above the patella, at the level of the knee, just below the tuberosity of the tibia, and of the calf, and the inside length of the leg from the gluteal fold to the apex of the internal malleolus. Skin colour, hair colour, and eye colour were also recorded in numerous variations of each primary hue, as also the weight of the individual.

We quote this list of measurements almost in full by way of indicating the extent of the inquiry. The army anthropologist may possibly scoff at some of them as being solely of sartorial interest, but the value of the majority is fully obvious. For instance, in grouping men for marching purposes, equality of leg length must certainly be of more importance than equality of total height, and men whose total height is low, but whose chest measurements and weight are relatively high, would carry packs much more easily than tall men of a light general build.

No head or foot measurements seem to have been taken, and this seems curious, both as regards the ostensible and the real object in view. The right fitting of helmets, caps, and foot-gear is certainly of military importance, and important also from the point of view of army outfitters.

In regard to the standard measurements, we note that the mean stature of the first million recruits, both white and coloured, was just under 5 ft. 7½ in., their mean undilated chest measurement just over 33 inches, and their mean weight just over 10 st. 1½ lb. Most of these men, of course, were quite young.

When classified according to the area of the United States from which they were drawn, or according to the races to which they were considered to belong, men from mountain areas were found habitually to "run tall," while racially the order and mean stature of the principal eight European nations were as follows: The Scottish (67·92 in.), the English (67·75 in.), the Germans (67·73 in.), the Irish (67·46 in.), the Poles (66·70 in.), the French (66·37 in.), the Hebrews (65·71 in.), and the Italians (65·03 in.). The assignment of an individual to a particular race was on conventional lines.

The same nations are seen to fall into a very different order when considered from the point of view of robustness, this being a correlation of several measurements. When divided into two main groups, Nordic and Mediterranean, the latter supplies better figures than the former, but the exact order of the nations individually in point of robustness is seen to be Poles, Italians, Germans, French, English, Scottish, Irish. In regard to differences between coloured and white races, the chief point seems to be that men of colour tend to be from the waist downwards longer and stronger than the whites, and from the waist upwards the reverse. This may be a surprise to those who, having lived in Africa, tend to believe that the strong point of a negro is the thickness of his head, and his weak point his shins.

The tables relating to correlations between medical defects and the standard measurements do not seem to justify any very positive conclusions, so we content ourselves by saying that they uphold, on the whole, the old belief that an individual who, for his race, is of average height, weight, and chest measurement, is likely to be better fitted for rough physical work, such as soldiering, than one who is either unusually short or unusually tall.

In regard to the general importance of anthropology from a military point of view, the authors of the report consider that the experience gained in raising an army show that if ever the task has to be undertaken again by the United

[1] *The Medical Department of the United States Army in the World War.* Vol. XV. Statistics. Part I, Army Anthropology. Prepared under the direction of Surgeon General M. W. Ireland by C. B. Davenport, formerly Major, S.C., U.S.A., and A. G. Love, Major, M.C., U.S.A. Washington: Government Printing Offices. 1923. (Super-roy. 8vo, pp. 635, 139 tables. 1.75 dollars.)

States there should at the outset be appointed among the officers of the Medical Department a broadly trained anthropologist for performance of the following duties

1 Collaboration in drawing up schedules for the physical examination of recruits
2 Consultation on the taking of the standard measurements and observations on recruits throughout the country and especially at military camps and posts
3 General supervision of the service of taking identification data
4 Organization of the service of answering questions that may arise about the racial classification and racial differences of individuals

In regard to the duty last named, it seems probable that the authors had in mind the fact that at one time it was intended to form units and aggregations of units on racial lines in such cases questions concerning ration allowance and many other points might clearly have arisen

The analytical treatment of the basic data obtained is certainly remarkably complete and the volume as a whole a worthy companion of the first volume of the same history, to which attention was drawn some time ago

BISMUTH IN SYPHILIS

It is three years since bismuth was introduced for the treatment of syphilis, and sufficient experience has now accumulated to justify the appearance of such a book as *Le Bismuth dans le Traitement de la Syphilis*, by C LEVADITI It opens with an historical account of the discovery of bismuth as a remedy for syphilis, and with a summary of the properties of the metal, its toxicity, its absorption and its elimination Following this comes a chapter on experimental work on animals and then, the most important portion of the book, its use in clinical medicine The author takes in turn the primary, secondary and the tertiary stages of the disease and finally deals with bismuth in neuro-syphilis and in the inherited disease, citing cases to illustrate his thesis and render the account as practical as possible The influence of bismuth on the Wassermann reaction is then studied, and also its action on certain resistant forms of the disease in which mercury and arsenic have failed The last chapter discusses the different methods of administering the drug, its dosage, and the different preparations

Certainly the book has been written by a clinician who understands those points that are of importance to the practising doctor The general conclusion is that bismuth acts curatively, not only in the laboratory with respect to the infected rabbit, but also in the infected human being

PSYCHIATRY

In a volume entitled *The Borderland Some of the Problems of Insanity*,[2] Dr THEO B HYSLOP considers the difficult question of racial degeneracy He takes a frankly pessimistic view of the general mental status of the community He draws attention to the steady increase in the ratio of the certified insane to the population in England and Wales, and states that the American lunacy figures are even more startling than our own He reminds us that statistics only refer to lunatics under official cognizance, and that they do not include those who as imbeciles are yet permitted to remain citizens, the thousands who are on the borderland between sanity and insanity the weak minded the epileptic, the partially demented, the hysteric, the deluded the morally insane the drunkards and the neurasthenics who, having run their course all too soon are incapacitated from taking part in or adding to the physical and mental welfare of the race The author is of the opinion that if we were provided with statistics relating to those who by reason of mental infirmity are incapacitated from competition, or even aiding in their own survival we should realize more completely the true state of affairs and one and all would rise in revolt at the insidious onset of a national dementia which ere long it may be too late to combat or even ameliorate

Dr Hyslop has raised a question of paramount social importance, but we should be reluctant to accept unhesitatingly his views as to the mental decadence of the community, not because they are unpalatable, but because there are insufficient data on which to base an opinion as to whether the general tendency is towards deterioration, mental and physical, or the reverse In an important paper[4] by Professor Kraepelin it is shown that the mental health of the community is determined by the simultaneous action of a great number of complicated, co operating, interacting and conflicting influences and no one can say whither the resultant of the forces is tending In order to determine whether the general tendency is towards decadence on the one hand, or progressive development or productive and resistive power on the other, psychiatric investigation on a large scale as Kraepelin points out, is necessary We need what he describes as a "mass psychiatry," having at its disposal statistics in their widest scope to provide the foundations for a science of mental health—a preventive psychological medicine for combating all those mischiefs that we group under the head of mental degeneracy Without such an inquiry we are scarcely in a position to admit or deny the accuracy of Dr Hyslop's conclusions Facts alone will enable us to estimate the extent of mental instability amongst the community, the degree to which it is increasing or diminishing and the efficacy of our methods of dealing with it Much more is needed than figures relating to the notified insane, but, as was pointed out in the Report of the Board of Control for 1923 the present increase of insane under care by no means necessarily connotes any increase in the incidence of insanity among the general population

The book as a whole lacks continuity of theme and consists of isolated essays treating of various aspects of psychiatry Some of the chapters deal with subjects of purely technical interest and others are more popular in their appeal The book contains a number of repetitions, and in one instance a long passage covering nearly two pages appears in different chapters Dr Hyslop has rendered a service to the community by bringing the problem of degeneracy into the foreground but his treatment of the subject is too discursive to be really forceful and convincing

NOTES ON BOOKS

OPERATIONS upon the sympathetic ganglia and nerves are under trial in connexion with attempts to relieve angina pectoris, exophthalmic goitre varieties of neuralgia and circulatory disturbances, chronic ulcerations, and the employment of regional anaesthesia None of the foregoing proposals have become established procedures, but attempts require from the surgeon a preliminary knowledge of the anatomy and physiology of the vago-sympathetic ganglia, as well as of the results which have followed surgical undertakings The recent book on the surgery of the vago-sympathetic,[5] by Professor BRÜNING and Dr STAHL, supplies a very full account of this subject together with excellent illustrations including some coloured ones, a full table of contents thirty eight pages of bibliography, and a subject index Under the several heads appended to the systematic description are abstracts of cases—both those under the authors, numbering sixty six and others referred to in the bibliography The book forms a most thorough going exposition of its subject

The third International Conference on Leprosy was held at Strasbourg at the end of July, 1923 under the presidency of Professor Jeanselme of Paris, Sir Leonard Rogers being the honorary president Delegates from all parts of the world assembled, including a representative of the Ministry of Health A detailed report of the conference has now been published the lateness of its appearance is stated to be due to the unavoidable delays and difficulties in securing accurate translations of the papers which were read in other languages than French The volume deals with leprosy under six

headings—statistical, etiological, pathological, therapeutic, prophylactic, and legislative It is well indexed, and many illustrations are included Besides forming a record of an important congress it constitutes a useful reference book on leprosy, about which far more information is now available than was the case when the previous conference was held at Bergen in 1909

The fact that a third edition of *Kystoskopischer Atlas*,[1] by Dr WOSSIDLO, has appeared is a sufficient proof that the work has found favour with those interested in cystoscopy The new edition differs very little from the old, and the author has avoided the temptation, to which all authors are exposed, of adding to the length of his work The only addition of any note is the section on bilharzia of the bladder. To the coloured plates at the end of the book have been added pictures of syphilitic ulceration of the bladder and bilharzia.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE PRINCE OF WALES on December 16th presided over the distribution meeting of the King Edward's Hospital Fund for London, and read a letter from the King expressing satisfaction that the hospitals of London would have before long 2,000 more beds than before the war, and that the King's Fund was helping to provide another 300 beds, including 53 for accident cases

Lord REVELSTOKE, honorary treasurer, reporting the amount received for general purposes, said that the only serious decrease was in the general fund legacies, which were always liable to fluctuation On the other hand, anonymous donations of £7,000 and £5,000 had been received, a contribution of £15,000 had been made by the British Charities Association, while other subscriptions and donations had been well maintained It was possible, therefore, to maintain the ordinary distribution at the figure authorized in 1923—namely, £235,000 It was essential, he thought, that the yearly distribution should correspond with the income In accordance with the decision of the council last July that the proceeds of the legacies of the late Mr and Mrs Wells should be applied in aid of hospital extensions and improvements, the special distribution of £81,000 was available from this source The Wells legacies were expected to amount to about £200,000, of which only £72,000 had yet been received A considerable proportion of the £81,000 allocated at the meeting would not be actually payable for some time, in accordance with the conditions attached to the grants

Sir WILLIAM COLLINS, in making the annual statement on behalf of the League of Mercy, said that by the end of the year the League would be able to hand over £14,500, bringing the total so far subscribed by it to the King's Fund to £368,034 The League of Mercy had benefited by the generosity of the British Charities Association, which had entrusted the League with the distribution of £5,000 to the extra-metropolitan hospitals The League had been able to give the provincial hospitals £9,760, making a total to the extra-metropolitan hospitals of £64,769 the grand total for the last twenty-five years was thus £432,802

Grants to Hospitals and Convalescent Homes

Sir COOPER PERRY presented the report of the Distribution Committee The amount of allocation amongst hospitals, including their recovery and convalescent branches, was £233,000, equalling that of last year Besides co-operating in discussions and inquiries with regard to hospital accommodation, the King's Fund had taken practical steps towards the actual solution of the problem by helping the hospitals to carry out extensions that had been delayed by the war It had also increased the proportion of the ordinary distribution allocated to grants in aid of capital expenditure These grants this year amounted to £35,725, as compared with £30,100 in 1923, and £26,500 in 1922

Major HAROLD WERNHER, honorary secretary, presented the schedule containing the list of awards to hospitals (including recovery and convalescent branches)

The larger sums awarded include £13 250 to the London Hospital, £11 500 to Guy's Hospital, £10,500 to St Thomas's Hospital £8 500 to [illegible]'s College Hospital £8,300 to the Royal £8 000 to St Bartholomew's Hospital £7 50[illegible] Hospital £7 000 to St George's Hospital £6 5[illegible] Hospital, £6 400 to the Middlesex Hospital, £6 100 to the Hospital for Sick Children £6,000 to the Royal Free Hospital, £5 600 to the Miller General Hospital, £5 500 to St Mary's Hospital, £5 000 to the West London Hospital, £4,600 to the Prince of Wales's General Hospital, £4,500 to the Queen's Hospital for Children £4 450 to Queen Mary's Hospital for the Last End, £4 000 to the National Hospital for the Paralysed and Epileptic, and £4 000 to Charing Cross Hospital

Sir COOPER PERRY then presented the report of the Distribution Committee with reference to convalescent homes not attached to particular hospitals, this showed that £2,000 had been distributed during the year Major General Sir CECIL LOWTHER, honorary secretary, presented the schedule of awards Sir COOPER PERRY then presented the report of the committee on the special distribution of the Wells legacies to date The list of grants made or recommended amounted to £81,000, which would increase the number of beds available for patients by 301, of these beds 53 will be reserved for accident cases Included in these grants were amounts of £25,000 to the Woolwich and District War Memorial Hospital, £16,000 to King's College Hospital, and £16,000 to the Miller General Hospital

Improvement in Hospital Finance

The PRINCE OF WALES called attention to the fact that the ordinary distribution this year of £235,000 had again been provided without drawing on reserves, and thanked the British Charities Association for its efforts in aid of the hospitals and for entrusting to the King's Fund the distribution of £15,000 for the London area There were three points of importance in the Distribution Committee's report The first was the enormous improvement in the ordinary finances of the hospitals of London Taken altogether, and omitting the combined appeal and one exceptionally large legacy, the annual deficit had been reduced from £175,000 for the year 1922 to £20,000 for the year 1923 This seemed almost miraculous when compared with the annual deficit of nearly £400,000 four years ago It indicated that the people of London were really attached to the voluntary hospitals, and were willing to make the necessary sacrifices to maintain them It was to be hoped, therefore, that the deficits still remaining would soon be abolished In the second place, the hospitals were being enlarged, and the King's Fund had been very active in this matter The number of beds, 13,000 in 1922, would be increased to 14,000 when the schemes now in hand were completed Further schemes were pending, and still others were only waiting for better times The Distribution Committee had selected for help those hospital schemes which had just reached the stage at which special assistance would be most valuable The third point was the provision of beds for accident cases, the report of the Ambulance Cases Disposal Committee of the King's Fund had been translated into action by both the London County Council Ambulance Service and the Distribution Committee of the Fund Another forward movement by the King's Fund was the extension of the area of operations from a radius of nine miles round Charing Cross to a radius of eleven miles round St Paul's Cathedral, bringing in more of the eastern districts and adding to the liabilities of the Fund The Propaganda Subcommittee, under the chairmanship of Lord Burnham, had been very energetic, partly in connexion with direct propaganda for the hospitals and the King's Fund, and partly in regard to money-raising schemes including propaganda work Arrangements were now being made for lectures in schools to spread among the young of all classes a knowledge of the work of the hospitals and the debt owed to them by the whole community A panel of expert lecturers had been secured, and applications from schools were being received Another subcommittee, with Sir Richard Gregory as chairman, had arranged a series of popular scientific lectures in various parts of London early next year

Viscount CAVE, in moving a very cordial vote of thanks to the Prince of Wales for presiding, alluded to the keen personal interest he had taken in the Fund, and to the encouragement to be derived from his speeches The motion was carried with acclamation

British Medical Journal.

SATURDAY, DECEMBER 27TH, 1924

LISTERISM AND WAR WOUNDS

The authoritative life of Lister by his nephew Sir Rickman Godlee appeared towards the end of 1917 and a detailed review was published in the issue of the BRITISH MEDICAL JOURNAL for December 1st of that year (p. 725). We then said that for the production of a successful biography two conditions were essential—a fit subject and a proper amount of style in the representation—and said that the volume fulfilled both conditions, observing that Lord Lister is one of the great figures in the history of the healing art there can be no question and that Sir Rickman Godlee has provided a memoir that will live as one of the great biographies every competent critic must cordially agree. A second edition was called for within a few months and a third has now been published.[1] For the most part Sir Rickman Godlee says the book remains as it was first published. A little new material has been added partly in the text but chiefly in notes. He has however written a new chapter with the title Postscript 1924 it is founded upon information supplied to him by friends on the staffs of hospitals in England Scotland Ireland Canada America and Switzerland it will revive many memories, and will stimulate thought.

At the outbreak of the war of 1914-18 surgeons were of course far better equipped in knowledge and resources than in pre-antiseptic days. Yet early experiences with gunshot wounds were so disturbing that a feeling of dismay at their inability to check virulent infection swept over all. Cases superficially similar had been under care in civilian practice. Compound fractures were no new problem and yet the military cases were doing so much worse than had been anticipated. What was the essential difference? Were our teachings fundamentally unsound? Had we forgotten lessons we thought we had learned? The obvious thing to do was to go back to Lister to re-examine the writings of the Master and particularly his early papers on compound fractures.

Few people had read and fewer remembered from personal contact the precise technique which Lister himself had advocated for these cases. The younger generations had been brought up on asepsis had been educated in a milieu of high pressure sterilizers rubber gloves masks and dry wounds. Only the elders remembered and only they employed the antiseptic lotion for the wound and the wet towel. When it came to antisepsis it became necessary for the generation actually on the field of battle to work backwards from their bacteriological knowledge to where Lister had been in the sixties. They knew nothing or next to nothing of the rubbing of the wound with pure carbolic of the pastes that Lister tried or the various antiseptic solutions with which an attempt had been made to sterilize infected wounds. To add to their discomfiture a most respected bacteriologist wrote most convincingly on the futility of antiseptics in general. What was the surgeon to believe? Some were for going back completely to the technique described in Lister's early papers—the use of pure carbolic and so forth. This idea found favour with few carbolic is no longer a favourite antiseptic. More were attracted by the salt treatment which certainly appealed to the intelligence, even though the results were disappointing. New antiseptics were sought and discovered. Dakin came in and its powder cupad, and then the Carrel-Dakin treatment. The latter would most certainly have made a strong appeal to Lister himself. In it is fulfilled one of the principles for the application of which he searched so long—the continuous removal of an antiseptic solution which had no markedly deleterious effect on the tissues. And then came Bipp. In general utility the use of this paste far transcends Carrel-Dakin. In this preparation devised by Mr. Lutherford Morison we have an antiseptic paste such as Lister sought and would almost certainly have devised had he been in his heyday in these later troubled times. It is curious that Sir Rickman Godlee makes no mention of it in this book though he pays handsome tribute to the excision of wounds. On the utility of excision there can be no question and most who worked in France felt in the last months of the war that the wound problem at long last had been solved. Wound excision at the earliest possible moment with primary, delayed primary or secondary suture as the nature of the wounds demanded antiseptic treatment (Carrel-Dakin or bipp) for those already too heavily infected for excision to be the wise course these were the principal methods finally adopted as routine. But it required fully three and a half years for them evolution on an unprecedented mass of human material.

[1] *Lord Lister.* By Sir Rickman John Godlee, Bt., K.C.V.O., M.S., F.R.C.S. Third edition, revised. Oxford: The Clarendon Press. 1924. (Med. 8vo, pp. xvi + 645, illustrated, 21s. net.)

INSANITY IN NEW YORK STATE

The report of the State Hospital Commissioners of the State of New York for the year ending June 30th, 1923, is one of the legislative documents published by the State in 1924. The commissioners, three in number, hold much the same position as Commissioners of Lunacy hold in England. The State hospitals to which the report refers are the hospitals for the insane. Thirteen of them are classified as civil hospitals, two as hospitals for the criminal insane, and twenty-eight as licensed and seven as unlicensed institutions. All were visited during the year by the commissioners. The total number of patients under treatment in them was 49,663 in the civil hospitals, 1,698 in the hospitals for criminal insane, and 1,521 in the private institutions. The recovery rate among first admissions was 26·4 per cent. but only 3·7 per cent. of the total under treatment. The death rate among the latter was 79·7 per 1,000, the death rate among the senile, cerebral arterio-sclerosis, and general paralysis cases being as high as 338·6, 363·3, and 321·1 per 1,000 respectively. By far the greatest number of those under treatment were cases of dementia praecox (12,754 males and 13,730 females), the death rate was 33·7 per 1,000. The nearest approach to these numbers were 1,919 male and 3,769 female manic-depressive cases.

Alcoholic patients are classified in the report as those under treatment for the intemperate use of alcohol, and it is not clear if this means insanity due to alcohol, delirium tremens or simply intemperance without definite morbid conditions, for the report notes that in a previous year the alcohol patients included moderate drinkers. Whatever is meant the cases in the hospitals numbered 1,286 males and 501 females with a death rate of 45·9 per 1,000. The only other cases in excess of these numbers were 2,342 of general

paralysis and 2,041 senile cases Patients undergoing treatment for the use of drugs and other exogenous toxins were remarkably few—50 males and 38 females, with 6 deaths We naturally look to a report of this kind to disclose facts bearing on the effects of the American prohibition legislation, which came into force in January, 1920 With the exception of the year 1910, when moderate drinkers were included in the total of 2,172 first admissions for intemperate use of alcohol, the admissions year by year during 1911, 1912, 1913, 1914, and 1915 were respectively 1,384, 1,370, 1,421, 1,285, and 1,164 There was then a drop to 907 in 1916, but a big rise to 1,452 in 1917 There was a decline to 1,104 in 1918, and the figures in the five subsequent years were 965, 803, 822, 879, and 886 The percentage of admissions for intemperate use of alcohol amongst total admissions was 20 9 for males and 4 0 for females in the year 1923 This percentage among males has steadily declined since 1911, but showed no marked decline among females until 1914, when it dropped from 11 1 to 8 8 During the three years 1921, 1922, and 1923, however, there has been a tendency to increase—from 18 9 to 20 9 in males, and 3 7 in 1920 to 4 0 in 1923 in females

Some interesting facts are also disclosed concerning the admission rate for all classes of insane persons in relation to population and to racial origin In 1903 it was 886 per million of population, the lowest rate on record was 677 in 1902 and the highest 944 in 1917 The statistics, however, do not give evidence of progressive increase or decrease in admissions to the State hospitals, although the number of criminal insane admitted in 1923 was higher than in any previous year since 1909, with the exception of the years 1913 and 1914 The statistics of race and nativity are interesting, but require fuller explanation than is given in the report before any conclusions can be drawn from them As regards nativity, 55 2 per cent of the 6,900 first admissions in 1923 were born of parents natives of the United States, and 44 5 per cent of foreign-born parents Only 18 admissions were of unknown origin By far the largest number of "foreign born" were of Irish or Italian parentage—namely, 513, or 16 7 per cent, Irish, and 467, or 15 2 per cent, Italian No other nationality, except German with 11 9 per cent and Russian with 11 2 per cent, reached a percentage of double figures The English "foreign-born" percentage was 4 5 and the Scottish 1 6 The marked difference in these figures may no doubt be due to a preponderance of Irish and Italian "foreign-borns" in the State of New York, but unfortunately the report throws no light on this When the first admissions are classified according to racial origin, as distinct from "foreign-born" nationality, the predominance amongst the insane of cases of Irish origin is still more marked, but this again may be due to an Irish predominance in the population The per centages among the 6,900 first admissions in 1923 were 17 0 of Irish origin, 11 4 German, 10 8 Hebrew, 8 0 Italian, 5 8 Slavonic, 4 6 African, and 4 4 English, 25 7 per cent were of mixed race and 3 5 per cent of unascertained race

Besides these and other statistical analyses of the cases under treatment and first admissions, the report contains an account of the scientific work of the State Psychiatric Institute, but most of it has already been published in psychiatric and other journals The chief scientific investigation recorded in 1923 was the relation of focal infections to the functional psychoses The investigation had been going on for the previous three years, and has now been concluded The results showed that focal infection, whether from the teeth, stomach, intestine, or elsewhere, could not be considered a specific factor in these psychoses Another investigation in 1923 was into the effect of *Bacillus acidophilus* therapy in chronic constipation and diarrhoea It was prompted by a desire to find some method of dealing with intestinal stasis and possible toxaemias by other than radical surgical methods In the course of this investigation the view that the presence of indican in the urine is of clinical significance was disproved, as indican was often excreted with no accompanying constipation, and no evidence of its presence was found in the urine of two patients who had had no normal defaecation for four months There are other interesting notes in the section of the report dealing with the work of the Psychiatric Institute, especially with regard to the absence of abnormality in the brains of patients dying from dementia praecox and the pathological changes found in the brains of epileptics

Overcrowding is stated to have been worse in 1923 than it had ever been in the history of these institutions Attempts are being made in several directions to remedy this The State Legislature passed a bill during the year for the issue of bonds to the amount of 50 million dollars in order to replace the old, worn out, and inflammable State hospital buildings The need of this was brought forcibly to notice by a disastrous fire, in February, 1923, in the Manhattan Hospital for the Insane, a hospital of 4,665 beds, when twenty-two patients and three of the staff perished Another measure for reducing the number of patients was the appointment of a medical examiner to investigate and remove aliens who may have been admitted from other States or countries But the chief measure was the discharge of patients to their homes, where they were kept under medical supervision, or their transport from the overcrowded metropolitan hospitals to hospitals up country In connexion with the treatment and supervision of patients on parole in their own homes, forty three out-patient clinics for mental diseases have been established in large centres of population They are regarded as an important measure also for decreasing the incidence of mental diseases Persons with premonitions of mental disturbance are taken in hand in them by medical experts, and also receive assistance from social workers, of whom there are twenty eight attached to the hospital staffs Effective work has in this way been carried out in preventing mental breakdown and promoting mental health

CHLORINE TREATMENT OF CERTAIN INFECTIONS

THE use of chlorine in certain infectious diseases, such as influenza and tuberculosis, is no new suggestion, conflicting reports as to its value in the latter disease were obtained from British tuberculosis specialists before the war On *June 2nd, 1923* (p 958), we reported experiments that had been made in the University of Arkansas, which were stated to support the conclusion that the daily breathing of air containing small amounts of chlorine acted as a preventive of influenza More recently Lieut.-Colonel E B Vedder and Captain H P Sawyer, of the Medical Corps of the United States Army, investigated the value of chlorine, and came to the conclusion[1] that inhalations of chlorine of a concentration of 0 015 mg per litre had a definitely curative value in common colds, influenza, whooping-cough, and other respiratory diseases in which the infecting organisms

[1] *Journ Amer Med Assoc*, March 8th, 1924 p 764

were situated on the surface of the respiratory mucous membrane. They added that the apparatus for this treatment could be employed in general practice. This report excited considerable interest, and individual practitioners in America, as well as hospitals and health departments began to test the treatment on a large scale. Two clinics were established in New York City, and a report of their results was published in the health bulletin of the City of New York. An article in the *Journal of the American Medical Association* of December 6th 1924 (p. 1851) contains the information that only 6·5 per cent. of 506 patients with various respiratory diseases reported themselves as cured as compared with 71·4 per cent. of 931 patients stated in the original paper by Vedder and Sawyer to have been cured. Of the patients treated in the New York clinics improvement was reported in 53 per cent., but it is remarked that no great importance can be attached to this, since patients with minor respiratory infections tend to improve naturally to some extent. It is stated that in acute cases the claims made for chlorine treatment cannot be sustained. In whooping-cough 18 cases with 12 controls were studied; the chlorine method of treatment was not found to present any appreciable advantages, and no benefit was reported in asthma and hay fever. In fact, three patients with asthma became decidedly worse while under treatment. The conclusion is reached that though the work of the original investigators appears to have been conducted in a most careful and scientific manner the original claims in favour of this treatment have not been substantiated. Numerous investigations are being made elsewhere in America the result of which must be awaited before a final decision can be reached at present however chlorine inhalation treatment cannot apparently be recommended in respiratory disease.

MINERALIZED METHYLATED SPIRIT

SINCE May 1st, 1924 mineralized or denatured methylated spirit (spiritus methylatus) has consisted of a mixture of spirit 90 per cent. wood naphtha 9·5 per cent., crude pyridine 0·5 per cent., mineral naphtha 0·375 per cent. and a small proportion of colouring matter (methyl violet). This is the only methylated spirit allowed to be sold by retailers. Pyridine as a denaturant was introduced by the Board of Customs and Excise in accordance with a promise made by the Government to make such changes in the composition of methylated spirit as would render it quite undrinkable without destroying its usefulness. It soon became apparent however that the new methylated spirit was by reason of its pyridine a skin irritant. The pyridine renders the spirit not merely nauseous and poisonous, but unsuitable for use as a lotion to harden the skin and prevent bed sores; it is also incompatible with picric acid. The matter was raised in the Annual Representative Meeting of the British Medical Association at Bradford last July and a resolution was adopted asking the Council "to consider the alteration in the composition of methylated spirit by the addition of pyridine which renders the spirit unfit for use as an external application to the skin and unpleasant to burn on account of the disagreeable odour produced and to take such steps as are possible to get the use of pyridine discontinued if the spirit is supplied to the order of a medical practitioner." In accordance with this resolution (as mentioned in the SUPPLEMENT of November 8th) the Board of Customs and Excise was urged to take immediate steps to meet the situation. The department replied that it was hoping to arrive at a solution of the difficulty in a short time but in the meanwhile applications from hospitals and bona fide nursing homes for permission to receive industrial methylated spirit—a mixture of 95 volumes of strong spirit with 5 volumes of wood naphtha—would be considered, provided the spirit was used strictly for medical and surgical purposes and not for burning. This of course, touches only one side of the matter and complaints from medical practitioners continue to reach the head office of the Association. Communications have been received also from the Pharmaceutical Society indicating the concern felt by pharmacists at the harmful effects of the compulsory addition of pyridine to methylated spirit. The Board of Customs and Excise has informed the Medical Secretary within the last few days that it is proposing to issue regulations dealing with this question and will give the Association an opportunity of commenting on the regulations before they are issued.

THE SUDHOFF CELEBRATION

DR KARL SUDHOFF the medical historian, was born on November 26th 1853. Imbued with admiration for his services, Dr Charles Singer and Dr Henry E. Sigerist of Zurich have shown that medicine has no geographical limitations or shame in national enmities by celebrating his seventieth birthday in a collection of eighteen *Essays on the History of Medicine*[1] written in their own languages by nineteen contributors from six countries—England, America, Germany, Austria, Italy, and Switzerland. The editors have in no way pulled their punches for Dr Charles Singer contributes two articles—one. The origin of the medical school of Salerno, the first European university, an attempted reconstruction, in collaboration with his wife, and a second with Dr E. C. Streeter of Harvard on fifteenth century miniatures of extramural dissection. Dr Sigerist writes on the birth of Western medicine in the section devoted to the Renaissance, and is responsible for the bibliography of Professor Sudhoff's writings, which occupies twenty-seven pages and numbers more than 680 items. The volume is dedicated to Professor Sudhoff in a short and graceful letter such as Sir Clifford Allbutt writes with a charm all his own. The frontispiece is a half-length photograph of Professor Sudhoff and the articles are arranged under the five headings of antiquity, the Middle Ages, the Renaissance, modern times, and general subjects. The first and the longest article occupying more than a sixth of the volume is on prehistoric attempts to avoid and abolish epidemic diseases and is followed by Dr Lynn Thorndike of Cleveland, Ohio, on Disputed dates, civilization, and climate, and traces of magic in the scientific treatises ascribed to Theophrastus." The section devoted to the Middle Ages contains Dr E. O. von Lippmann's essay on the history of alchemy; Dr and Mrs Singer's account of Salerno and Dr F. T. Withington's translation of Roger Bacon *De Erroribus Medicorum*. Among the articles dealing with the Renaissance times there is a well illustrated account of "The 'Epitome' of Vesalius on Vellum in the British Museum" by Mr W. G. Spencer. A specially interesting article is that by Dr Fielding H. Garrison on The newer epidemiology. Altogether the editors must be heartily congratulated on the success of the volume.

CONTROL OF VENEREAL DISEASE

AT an Abolitionist Congress in Graz, Austria, in September Dr W. F. Vel-huyzen chief medical officer of health for Amsterdam read a thoughtful paper entitled 'Can venereal diseases be dealt with in the same way as other infections?' The paper has been translated for publication in *The Shield*, the official organ of the

[1] *Essays on the History of Medicine*. Presented to Karl Sudhoff on the Occasion of his Seventieth Birthday, November 26th 1923. Edited by Charles Singer and Henry E. Sigerist. London: Oxford University Press; Zurich: Seldwyla. 1924. (Royal 8vo, pp. viii + 478. 36 illustrations. 25s. net.)

Association for Moral and Social Hygiene in this country As the question of compulsory notification of these diseases is attracting increasing attention, and was recently debated at a conference at the Wembley Exhibition, the views of the health officer of the largest city in Holland are worth indicating He says that the reporting of cases by doctors in attendance has a double object (*a*) "to keep the authorities informed of the amount of disease in the community and to enable them to judge of the success of the measures taken against it", and (*b*) "to enable them to take whatever action seems useful in regard to infected individuals" As regards (*a*) he is of opinion that statistics obtained by compulsory notification are no more reliable than those from hospitals and polyclinics, and from information supplied by physicians willing to co-operate He declares that in Denmark compulsory notification of syphilis provides information which is considered so unreliable that alongside this legal system another system has been established, based on the voluntary co-operation of the medical profession All this, however, relates to compulsory notification by numbers, not by names, and he considers this quite useless Concerning notification by name, he takes the well known ground that it is a violation of professional secrecy, that absence of secrecy "would bring mischiefs which no possible advantages could compensate," and that many sufferers under risk of exposure would prefer to do without treatment Notification limited to persons who, after consulting a doctor, fail to carry out his treatment or leave it off too soon, is next considered by Dr Velthuyzen He sets forth what he regards as the argument of those who support this limited notification, including rigorous hospital isolation of cases not able to be dealt with suitably otherwise owing to social factors, and the isolation of infected prostitutes Even here, however, Dr Velthuyzen has certain objections into which want of space forbids our following him The next question discussed is the medical examination of suspected persons, just as school children or teachers suspected of harbouring the diphtheria bacillus are examined But here also Dr Velthuyzen is in opposition, and he summarizes his own experience thus "At Amsterdam, thanks to the devotion of doctors, nurses and the social worker attached to the polyclinic, we have obtained this remarkable result, that 95 per cent of the syphilitic men and 85 per cent of the women have remained continuously under treatment at the clinic and polyclinic during the two years that this system of collaboration has been established These figures are certainly not surpassed by those obtained in countries where compulsory treatment is in force"

SEWAGE TREATMENT IN THE UNITED STATES

ABOUT the middle of the last century it was considered that broad irrigation was almost the last word in the treatment of the sewage of large communities Large sewage farms were constructed, and the sanitary authorities of the day had visions of large profits accruing from them, with a welcome reduction in the local rates Very soon these broad acres became waterlogged, and a double system of sewers was advocated, the aphorism, "the rain to the river, the sewage to the soil," slipping glibly from the tongue of the sanitary engineer The local authorities were soon disillusioned, and the sewage farm was found to be a very costly enterprise It was displaced by a variety of methods of treatment, each having for its object the clarification of the sewage and the production of an effluent sufficiently pure to be discharged into a water course This appears to have been the stage at which the scientific treatment of sewage was entered upon in the United States of America, and a valuable report has recently been issued by the United States Public Health Service on fifteen representative sewage treatment plants in that country Twelve of these plants are modifications of what are known as septic tanks, and three are the more modern method of activated sludge treatment The report is by three officers of the Public Health Service—Mr H H Wagenhals, associate sanitary engineer, Mr E J Theriault assistant chemist, and Mr H B Hommon, sanitary engineer The engineers first spent about four days in inspecting and estimating the efficiency and economy of each plant, and obtaining information concerning the population served, etc The chemist devoted about sixteen days to laboratory studies on the spot, a large number of samples being taken and a series of about twelve analyses made, importance is attached to the fact that the same methods of analysis were adopted at all the plants A most valuable feature of the report is the detailed account given of the sampling methods used as well as of the analytical processes adopted The authors of the report do not appear to have considered themselves called upon to offer any very definite opinion on the efficiency or otherwise of any of the plants investigated, but the reader will have no difficulty in forming his own judgement from the elaborate tables of the analytical results obtained The only exception to the non-committal attitude mentioned is the guarded statement that the activated sludge process is the most recent promising development in the treatment of sewage, a very informing description is given of three such installations, each of which is yielding satisfactory results The value of this report as a contribution to the subject to which it relates can hardly be overestimated, for the investigations which it records have been carried out on such comprehensive lines that the fallacies inherent in the investigations of observers acting independently of one another have been reduced to a minimum

---

THE New South Wales Government has recently voted a sum of £2,500 a year towards the staffing and equipment of the department of obstetrics in the University of Sydney This department has hitherto been under a lecturer and three clinical tutors, but the University Senate has now established a professorship of obstetrics to which a salary of £1,100 a year is attached, and applications for the chair are being invited in this country and in Australia Further particulars may be obtained from the Agent-General for New South Wales, Australia House, Strand, London, who, on behalf of the University, will receive applications until Saturday, January 24th, 1925 It is understood that, as is usual in the case of all professorships of the University of Sydney, the Senate will have the assistance of a committee of advice sitting in this country

---

THE announcement we were able to make last week that the Earl of Balfour, K G , O M , F R S , has accepted the position of Chairman of the Medical Research Council will have been received with great satisfaction by the medical profession Lord Balfour is not only a man of the highest distinction in public life, but also one who has attained eminence in the department of science, to which he has given special attention The Council had its origin in the Research Committee set up under the Insurance Act of 1911, which provided that Parliament should vote one penny in respect of each insured person, and that the whole or part of this sum should be applied for purposes of research The first chairman of the Medical Research Committee was Lord Moulton of Bank, who held the office from 1914 to 1916, he was succeeded by Viscount Astor, who, again, was succeeded by Viscount Goschen In 1920 the Committee became the Medical Research Council directly

responsible to the Privy Council. Lord Cochrane was succeeded in March by the Right Hon. Edward Wood, who retired on his appointment to be Minister of Agriculture in the present Government. It is to the vacancy thus created that Lord Balfour has been appointed.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

THE House of Commons stood adjourned till February 10th. The following, which it carried on a motion for adjournment, for Christmas did not include any bills on medical or health subject.

The Safeguarding of Food.—Answering Mr. Percy Harris (Lib. Edmonton) on December 15th Mr. Neville Chamberlain, Minister of Health, said he was aware that in the county of Dublin during the year 1919 10 children were killed and over 60 other persons injured by toxic antitoxin administered in connexion with the Schick test for diphtheria, and that in Vienna 72 infants died after an injection of toxin-antitoxin. In these cases the fatal doses were due to careless technique or to a particular batch of the remedy. The question of care had been emphasized in the report of the chief medical officer of the Ministry of Health for 1923. Mr. Broad urged the Minister to withdraw the memorandum (No. 70/Med.) issued by the Ministry in 1922. But Mr. Chamberlain saw no necessity to do so. The memorandum was concerned with Mr. Broad's argument to children in Poor Law institutions, but had general reference to residential schools and institutions.

Puerperal Mortality.—On December 17th Sir Kingsley Wood replying to Dr. Fremantle said that in 1923 deaths certified to pregnancy and childbirth, numbering 2,202, or 3·81 per 1,000 births, the average annual ratio from 1911 to 1920 was 5·49 per 1,000 births; after correction for comparability the ratio for 1923 was 3·6, a decrease of 3 per cent. compared with a decrease of 5 per cent. in the death rate of females between 15 and 55 years from all causes. A circular on maternal mortality had been issued by the Ministry of Health on June 30th, and local authorities were urged to take action with a view to lessening the risks involved in childbirth. The Minister proposed to await the result of the circular before considering further action.

In reply to other questions Sir Kingsley Wood said that eight local authorities had received powers to supervise all maternity homes in their areas. The Minister of Health hoped to introduce legislation on this subject.

Hot Years, Winds and Early Illness.—Dr. D. Shiels (Lab. Edinburgh East) during the debate on the Address referred in a maiden speech to the controversy about the prevalence of tuberculosis in districts exposed to the rain-bearing winds, and after praising the system of building houses with hollow outer walls concurred in the declaration previously made by Dr. Fremantle that tuberculosis could be stamped out in a generation.

Notes in Brief

The Minister of Health is advised that further knowledge is required before any definite opinion could be expressed on the alleged discovery of the causal organism of scarlet fever or the consequent test of susceptibility to the disease and of the specific character of the toxin and antitoxin. These matters were under investigation by the medical staff of the Ministry.

No promise can be given of the introduction of a Smoke Abatement Bill before 1926.

The regulations to be issued for carrying out the principal recommendations of the committee on the use of preservative in food will not, according to present plans, make it an offence to use arsenic in the preparation of cocoa nor soapstone in baking powder.

The average age of death of Sheffield grinders varied between 35·9 in 1918 and 52·9 in 1920. The total deaths between 1914 and 1923 were 1,135, of which 524 were due to pulmonary tuberculosis or other fibroid disease.

Since January 1924 eighteen deputy commissioners of medical service under the Ministry of Pensions have been notified that their employment will not be continued after April 30th, 1925. Fifteen of them served in the forces during the war.

No proposal for the abolition of the Ministry of Pensions is under the consideration of the Prime Minister.

The Minister for War, Sir L. Worthington-Evans, informed Dr. Fremantle on December 16th that only five candidates were accepted for the Royal Army Medical Corps in the July examination. He was personally endeavouring to remedy the present not satisfactory position with regard to the filling of commissions in the R.A.M.C.

The Minister of Health is considering the steps necessary to give effect to the principal recommendations of the Departmental Committee which recently reported on the adulteration of food and the labelling of imported food. The Minister proposes to regulate in particular the use of dyes in food and to do this chiefly by regulations, a bill not being thought necessary. Some time must pass before the regulations can be issued.

Sir Kingsley Wood, Parliamentary Secretary to the Ministry of Health, stated on December 17th that the Minister of Health did not propose to consider further extensions of the village settlements for tuberculous persons and their families until more experience was available on this particular method.

ADDISON'S ANAEMIA

THE ROBERT CAMPBELL MEMORIAL ORATION

THE Robert Campbell Memorial Oration was delivered in the Medical Institute, Belfast, on November 20th, by Dr. THOMAS HOUSTON, O.B.E., director of the clinical laboratories of the Royal Victoria Hospital. Dr. Houston prefaced his oration with an appreciative reference to the personal characteristics of Robert Campbell and to his work as a leader among the group of surgeons who revolutionized surgery in the Belfast School.

Taking as the theme of his oration that remarkable form of anaemia which was first described by Addison in 1855, Dr. Houston gave consideration to the question of the most appropriate name or Addison himself, for the disease in place of the term "pernicious anaemia" which is now commonly employed and which was first used by Biermer in 1872. Although the American clinician Walter Channing in 1842 was the first to describe the disease in connexion with pathological conditions, neither he nor the puerperal state theories could by any doubt that no impartial critic on comparing Addison's original description with the one of Biermer and Channing would hesitate for a moment in giving the honour to the English physician whose account of the disease would pass down to all future students of medicine as a masterpiece of clinical description.

The Legal Factor

The first landmark in the study of the disease was undoubtedly Addison's clinical description, and now after the lapse of seventy years every word of that masterpiece of clinical observation still held good. In considering the etiology of the disease Addison laid stress on what he termed its idiopathic or, as we should express it, cryptogenic character, using that term "to distinguish the disease from cases in which there existed more or less evidence of some of the usual causes or concomitants of the anaemic state." The term was in the main still applicable at the present day. Although most writers admitted that a certain number of cases were met with as the result of such conditions as severe and prolonged haemorrhage, pregnancy, internal parasites and cancer, Dr. Houston explained the opinion that such cases became fewer as methods of clinical examination became more exact. There were, however, he admitted, two exceptions to the general tendency. In a number of cases of infection with the *Bothriocephalus latus* a severe anaemia might develop, having all the characteristics of Addison's anaemia, and in certain cases of cancer with secondary deposit in the bone marrow a similar blood picture had been observed in a case of this kind having been recorded by Dr. Houston himself in the BRITISH MEDICAL JOURNAL of November 14th, 1903. Besides these two conditions, the recognition of which constituted an advance on Addison's original conception, the influence of heredity as an important factor in the etiology of the disease had recently received considerable attention. A number of cases had come under Dr. Houston's notice in which the element of heredity was unmistakably present. In 1902 he had under examination a female patient exhibiting the characteristic symptoms a few years later he examined the blood of her sister and brother; all three patients died from anaemia. In a second case the patient's sister showed the characteristic blood changes, and there was a history of her father and uncle having died with the same disease. In a third case the patient's father, brother, and uncle died from the disease. It had recently been suggested by Hurst that the hereditary factor in such cases was dependent on achlorhydria, a condition which Hurst regarded as being constantly present, as always preceding the anaemia, and as being in most cases congenital. With the exception of one doubtful case, all Dr. Houston's observations tended to confirm Hurst's contention. Another feature which could now be added towards the completion of Addison's picture was the relapsing character of the anaemia—a feature which, in Dr. Houston's opinion was so marked that it could not fail to impress the clinical observer. In one case under Dr. Houston's care the patient, who was comatose from the anaemia, had had two previous

attacks, with an interval of five years between each She recovered from the third attack and remained well for five years, when she died in the fourth relapse This patient, therefore, lived for fifteen years after the first attack, and she stated that during the remissions she was perfectly well and able to attend to her household duties without fatigue Other analogous cases were cited by Dr Houston as having come under his notice, in which patients suffering from grave conditions, such as coma and cardiac failure, recovered and became to all appearance perfectly well, dying, perhaps many years later, from a recurrence or series of recurrences of the disease A point of considerable interest in connexion with some of these cases was referred to by Dr Houston as of prognostic significance—namely, the occurrence of oedema His conclusions, arrived at from a series of observations, were that a gain of weight in a case of Addison's anaemia, under treatment and showing no improvement in the haemoglobin, was to be regarded as an unfavourable sign, indicating dilution of the blood and consequent escape of serum into the tissues On the other hand, the symptom might mark a critical phase in the disease, and indicate the first step towards concentration of the blood Immediately after this sudden increase in oedema either a marked improvement was to be expected or a fatal issue

Another modern observation of importance was that of the frequent occurrence of glossitis William Hunter, who drew attention to the point, had shown that the disease was generally accompanied with glossitis at one period or another of its course, and had indicated his opinion of its importance by suggesting the term "glossitic anaemia" for the disease He believed that it was perhaps the most characteristic and constant of its symptoms In Dr Houston's experience the majority of cases exhibited the symptom at some period in the course of the disease, and in some cases irritability of the tongue was constantly present He had, however, seen a number of otherwise typical cases in which it had never occurred With regard to other symptoms, those originating in the gastro-intestinal tract, such as vomiting, diarrhoea, and abdominal pain, were generally very prominent, and the fact that they were of common occurrence had strengthened the belief that the disease was due to an intestinal toxaemia Byrom Bramwell had suggested, on this account, that the disease might appropriately be termed "gastro-intestinal-hepatic anaemia" The nervous symptoms associated with Addison's anaemia were of particular interest, but although the connexion between the disease and combined sclerosis had been much discussed, no real solution of the problem of their relationship had been reached It was claimed that all cases of true combined sclerosis had a total absence of free hydrochloric acid in the stomach, and the disease could exist for years without any anaemia, but as a rule an anaemia of the Addisonian type developed at some stage of its course A remarkable point in this connexion was that the paresis might become worse as the anaemia improved, and both the anaemia and the nervous symptoms were liable to remissions which appeared to be entirely independent of each other

The Blood Changes

If Addison's description marked the starting-point in the history of the disease, the second important chapter was undoubtedly the study of the concomitant blood changes, which received its impulse in the work of Ehrlich Ehrlich regarded the essential lesion of Addison's anaemia to be a megaloblastic degeneration of the bone marrow, due to some unknown toxin which tended to promote the embryonic type of blood formation One of the most striking features of the disease was the marked anisocytosis which is usually present, but this, as Dr Houston pointed out, was by no means characteristic, if however it were accompanied by a high colour index or an increased amount of haemoglobin per red cell, the condition was almost diagnostic of the disease It might be stated definitely that an increase of haemoglobin per red cell was characteristic of the disease Ehrlich regarded the presence of megaloblasts as being practically pathognomonic, but this view had been called in question, since the presence of these cells had been demonstrated in other forms of anaemia, particularly those occurring in cases suffering from repeated small haemorrhages Piney has recently endeavoured to revive Ehrlich's theory, but as Dr Houston pointed out, a difficulty arises in coming to a decision on the question owing to the frequent impossibility of deciding whether a given cell should be classified as a macro-normoblast or as a true megaloblast It could, however, be stated that the presence of one or two typical megaloblasts often turned the balance of opinion in favour of Addison's anaemia The changes in the number and proportions of the leucocytes had not, in Dr Houston's opinion, received the attention they deserved There was nearly always marked leucopenia, proportional in a rough way to the anaemia When a patient improved it was the rule to find that the leucocytes increased in number, and when the polymorphonuclears were greatly diminished the patient was usually in a grave condition It was quite usual in severe cases to find the total leucocyte count 1,000 per c.mm or under Examination of the blood serum had given important results Van den Bergh's test for bilirubin in the serum always gave an increased positive indirect result in Addison's anaemia, but not in cancerous and other forms of secondary anaemia This was, in Dr Houston's opinion, a very definite proof that haemolysis was a constant feature of the disease Clarke and Evans had shown that the serum in Addison's anaemia had a decreased protective power against haemolysis by saponin They found that this decreased protective power was more pronounced in Addison's anaemia than in any other condition investigated, and that it varied much during the course of the disease, but was an important factor in determining the rate of blood destruction These results have been confirmed by Dr Houston in severe types of the disease, but little diminution of the protective power was found to occur in milder cases

Pathogenesis

The third chapter in the study of Addison's anaemia concerned the origin, nature, and pathogenesis of the disease This chapter might be said to have been opened by Hunter He came to the conclusion that Addison's anaemia was a specific, haemolytic disease, that the main seat of the haemolysis was in the portal circulation, and that the haemolysis was probably due to a poison generated in the alimentary canal As evidence of the occurrence of haemolysis and as supporting the theory, Dr Houston enumerated the following (1) The severe and rapid anaemia without external loss of blood, (2) its occurrence in association with an apparently increased activity of the bone marrow, (3) and with an increased excretion of urobilin, (4) and an increased bilirubin content of the blood, (5) a marked deposit of haemosiderin in certain organs, (6) an increased phagocytosis of red cells, and (7) the fact that a blood transfusion did not always raise, but might even be followed by a fall in, the blood count The evidence was, on the whole, convincing, but did not, in Dr Houston's opinion, amount to absolute certainty

With regard to the second point in Hunter's theory—namely, that the haemolysis took place in the portal circulation, probably by a toxin absorbed from the alimentary tract—the argument for the first conclusion was the enormous amount and peculiar distribution of the haemosiderin deposits found in the liver But it had been shown by McMaster, Rous, Peyton, and Larimore that repeated introductions of small quantities of haemoglobin into the general circulation led to an identical siderosis The foundation of Hunter's doctrine was, therefore, somewhat insecure In Dr Houston's opinion, although there were other reasons for the belief in a toxin originating in the alimentary tract, the only good argument that they possessed of the alimentary origin of the supposed toxin was the similarity of the symptom-complex occurring in *Bothriocephalus* anaemia

Recently Hurst had advocated the theory that achlorhydria was the essential etiological factor in the disease, but it could not be said that the theory rested on anything approaching experimental proof On the other hand, Louisa Ashby had come to the conclusion, on experimental grounds, that there was little evidence of the presence of any toxin circulating in the blood in pernicious anaemia Her results seemed to show that the blood destruction which took

place in this direction was due to a speeding up of the natural methods of blood destruction in the body, rather than to any toxin. Another theory of the pathogenesis of Addison's anæmia which was of great interest was that of Dr Hastings Gilford. He had suggested that the disease was no more than a premature senescence of the blood forming organs. One of the main objections urged against the theory was that Addison's anæmia was rare in old age. Dr Houston, in agreement with Dr Gilford, regarded this as probably incorrect. He had seen a considerable number of cases of typical Addison's anæmia in old people, and believed that many would be found if they were systematically looked for.

Treatment

Dr Houston concluded his oration with a brief reference to treatment. He considered that iron should be tried first, commencing with small doses and not increasing them to any extent, except in cases that did not respond. Arsenic might also be given intravenously as novarsenobenzol (N A B), or hypodermically as sodium cacodylate, but the agent should not be pressed, and if a prolonged trial proved ineffective the administration of the drug should be discontinued. Hydrochloric acid in large doses should always be tried; it sometimes had a good effect on the indigestion, and might determine a remission of the disease. If these measures failed to produce improvement, blood transfusion would often be found to be of extreme value, in some cases producing a definite remission at once. In the case of repeated transfusions it was important that the donor's blood should be carefully tested against that of the recipient, it was insufficient merely to type the blood. In the event of inability to find a suitable vein, extensive cutting operations should be avoided, and intramuscular or subcutaneous injections resorted to. Dr Houston having found that these methods gave exceedingly good results. On general principles it was desirable to remove all septic foci, although Dr Houston had observed little effect on the course of the anæmia in many cases contra-indicating in this respect very markedly with cases of secondary anæmia. Finally, with regard to splenectomy, he had had no experience, but from a study of the literature he concluded that it was to be recommended in certain selected cases.

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER

(*Continued from page 1127*)

LUNACY ADMINISTRATION UNDER THE POOR LAW

At the resumed sitting of the Royal Commission on Lunacy and Mental Disorder on December 16th and 17th evidence was given on behalf of the Association of Poor Law Unions by the Rev. P. S. G. Propert, president of that body, Mr P. A. Leach, vice-president, Mr J. H. Ford, clerk to the guardians, Leeds, and Mr J. W. Flint, chairman of the Sheffield guardians.

Mr PROPERT stated that his experience as a guardian for thirty years showed that on the whole the lunacy laws in their relation to the Poor Law had worked smoothly and satisfactorily. He had been impressed by the absence of serious complaint.

The Chairman, Mr H. P. MACMILLAN, said that the Commission had been struck by the extent to which Poor Law administration had been brought into lunacy administration. Many felt that this was rather an unfortunate association. By utilization of the Poor Law machinery a person who became mentally sick and was received into a Poor Law institution became for the time being a pauper, whereas this did not happen if a person had some other complaint and went into a general hospital.

Mr PROPERT said that the Poor Law hospitals were becoming very popular. The Poor Law stigma was passing away. He agreed that it was desirable to assimilate the treatment of mental illness as much as possible to the treatment of other forms of illness, and in his own union (Fulham) by means of separate observation wards which were really small hospitals the Poor Law atmosphere had disappeared in this connexion although of course the administration was still Poor Law. Treatment without certification would be a great advantage. Whatever arrangements were arrived at with regard to certificates preceding detention they should be the same for the rate-aided as for the private patient. As to whether two certificates were necessary a good deal depended upon the qualifications of the doctor who gave the first certificate.

Mr LEACH urged the desirability that the number of persons dealt with under the Lunacy Acts when the proceedings taken proved abortive for one reason or another should be recorded in the reports of the Board of Control. He urged also that an alleged lunatic should have all the protection accorded under Section 13 of the Act. While there might not be such a high standard of medical skill for mental cases available in Poor Law institutions the standard of nursing was as high as that in mental hospitals or possibly higher.

Much of the remainder of the evidence of these witnesses was devoted to technical matters of Poor Law administration.

Licensed Houses

The next witness was Dr F. H. EDWARDS, medical superintendent, Camberwell House, who gave the Commission a history and description of the licensed house. He said that institutions of this kind came into legal existence in 1774, when they were spoken of as private asylums. The Act of 1774 laid it down that houses that were to receive the insane must be licensed by law and that people must not be received except under medical certificate. Previous to 1811, however, no certificates were required in the case of pauper patients who were received and detained in licensed houses without any formality whatever, and the only protection they got was due to the fear on the part of those detaining them that action might subsequently be taken for illegal detention.

The Chairman pointed out that both the number of licensed houses and the number of patients under treatment in them had progressively diminished. Dr Edwards said that there was a clear reason for that. The function of the licensed house formerly was largely that of receiving pauper patients under contract. During recent years, however, many large boroughs had provided themselves with mental hospitals, so that the licensed house in this respect had become less necessary.

Figures were put in showing that in 1847 there were 141 licensed houses, with 6,629 inmates of whom 3,996 were paupers; in 1914 there were only 68 licensed houses with 3,493 inmates of whom 638 were paupers; in 1923 there were 56 licensed houses with 2,068 inmates none of whom were paupers. The witness said that the reduction in number of licensed houses meant more particularly the elimination of the very small houses. The largest licensed house in the kingdom was one for 672 patients, and some of the small ones had as few as four. The need for the licensed house still remained, and indeed the number of these places was not sufficient or rather they were not distributed so as to cover the needs of the country properly. There did undoubtedly exist in a large section of the population a demand for the treatment of the insane in other than a public institution. Every country in Europe and America had its licensed houses under some name or other. Another cause which had contributed to their decline in number was that many of them were started by medical men particularly interested in the care and treatment of the insane, and on their death the licensed house which was their private property fell to their heirs who perhaps had not the same interest and so the house as an institution tended to disappear. The licensed house was carried on not for charity but for gain. But it met the needs of a section of the community who did not want any charitable aid, and at the same time did not want to place themselves or their relatives in a public institution. He explained that the licensed house fell into two categories—namely, metropolitan licensed houses licensed by the Commissioners of the Board of Control, and provincial licensed houses licensed by the local justices. He proceeded to describe the safeguards of the patient in the licensed house. To suppose illegal detention would be to connote a conspiracy between the doctors, the magistrates, and the visiting Commissioners. His own licensed house was visited eight times a year by the Commissioners.

Sir CECIL CHUBB, LL.B., gave evidence as the proprietor of the Old Manor House, Salisbury, the largest and one of the oldest licensed houses in the country. The house comprised nineteen separate houses which rendered classification very effective. The patients at present in residence numbered 501. The medical staff consisted of the superintendent and four officers. Patients were given every possible opportunity of speaking to the visiting authority in fact on the occasion of their last visit the Commissioners interviewed ten or twelve patients privately. He considered that the power of granting leave or absence was a useful provision at the stage of convalescence. On the question of policy as between private and pauper patients he thought the rate-aided patient should also have the advantage of two certificates.

The Chairman said that the Commission had been impressed by the divergent methods by which persons reached institutions for the insane. A possible course to recommend might be the institution of a single medical certificate in all cases with the reservation that where any doubt was entertained by the single doctor or by the judicial authority either one or the other should be entitled to call for a second or any number of opinions. This of course had the drawback that the decision as to the supporting evidence would in many cases be left to the discretion of the single doctor.

Sir Cecil Chubb said that the present preliminaries to a patient's reception had occasionally resulted in persons being brought to the institution who should not be there. His doctor had refused to receive such cases. There might have been a mistake in diagnosis such as the confusion of delirium tremens with insanity. He thought there should be a provisional order of short duration, say of three days, which could be extended. The existing code adequately safeguarded the patient in the matter of discharge. The total percentage of recoveries at the Old Manor House compared with direct admissions in 1923 was 31·64. The average rate of discharge from 1914 to 1923 had been 37 per cent. He added that since the Harnett case there had been many more applications for admission as voluntary boarders owing to the refusal of doctors to certify. Only the other morning a doctor had told him that he would not certify a case for £20,000!

Dr FRANK FAWCETT, medical visitor to licensed houses for East Sussex, described the procedure at his visitations, which took place

four times a year. Special attention was paid to recent admissions and every opportunity was given to patients for private interviews. The witness stated, further, that the patients were encouraged to say anything which was on their minds, and were given to understand that the visitors represented a means of communication with the outside world.

SIR JAMES BARR of Liverpool also gave evidence as a medical visitor, an office which he had held for forty years. In his view the provisions of the Act were efficacious as a safeguard against the undue detention of patients. Complaints were more frequent and emphatic from undoubted cases of insanity than from cases on the way to recovery. He agreed that there might occasionally be differing opinions as to when a recovering patient could be discharged. In the institution he visited there were only about six encouraged, because, if people were to understand that the benefits of an institution could be obtained without certification, cases would be received at an earlier and more curable stage. He did not see any special advantage in two medical certificates in all cases.

In reply to Sir Humphry Rolleston, who asked whether the witness had any suggestion to offer with regard to the protection given to medical men certifying, Sir James Barr said that he would like to have the legal protection increased although he had no specific recommendations as to how this should be done. At present medical men felt so strongly on this matter that, unless a man or woman was palpably and dangerously insane, they could not be got to certify, because they feared that the, might be liable at any time to have to withstand an action at law. On another question, he would prefer the mechanism for dealing with incipient cases to be attached to a mental hospital, rather than to a general hospital, the former would be more specialized, and the general atmosphere and surroundings would be quieter and more congenial to the patient.

The Commission adjourned until January 13th, 1925.

England and Wales.

UNIVERSITY OF LEEDS CELEBRATION WEEK

THE celebration week in connexion with the jubilee of the Yorkshire College of Science and the coming of age of the University of Leeds opened on December 15th with a ceremonial gathering at the University in the morning, over which the Duke of Devonshire, Chancellor of the University, presided. Addresses were given by the Vice-Chancellor, Dr J B Baillie, and Sir Dugald Clerk, who was on the staff at the opening of the Yorkshire College fifty years ago. Sir Berkeley Moynihan, professor of surgery in the University, speaking at a reception at the medical school in the evening, gave a brilliant account of the history of medicine in Leeds from William Hey, one of the founders of the Leeds General Infirmary, in 1767, to the present day. At a dinner held in the Town Hall, in the evening, the Earl of Balfour, Chancellor of the University of Cambridge, proposing the toast of "The University of Leeds," described the ideals of the modern university. He was convinced that of all the instruments now in existence for the material advancement of mankind, science, with its many applications, was incomparably the greatest. The teaching of science, however, was not the whole nor perhaps the vital function of a modern university. Specialization was necessary, but it must be accompanied by a wide and generous general culture, acquired not only in lecture theatres, but also in the social centres of university life. A reception of delegates from universities and learned societies was held on December 16th, when honorary degrees were presented to Lord Balfour, Mr E G Arnold, Pro-Chancellor of Leeds University, Sir Berkeley Moynihan, Sir Michael Sadler, formerly Vice-Chancellor of Leeds University, and now Master of University College, Oxford, Professor J B Cohen, Dr J D Eddison, formerly professor of medicine in Leeds University, and others. In the evening two portraits of Sir Michael Sadler were presented to him. Mr Arnold, who presented the portrait, which is to be hung in the University, said that a memorial of the great work performed by Sir Michael during his vice-chancellorship from 1911 to 1923 had been organized, and as a result this portrait would be placed in the great hall, a replica had been painted for Sir Michael himself, and a fund of over £600 had been provided for the relief and help of necessitous students. Sir Berkeley Moynihan, speaking on behalf of the medical department, said that their tribute to Sir Michael Sadler might well be, "That he has enriched greatly the traditions which, planted nearly a century ago in the soil of our school of medicine, have taken deep root in the loyal service of our whole University, and in the days to come will probably flourish, a great heritage to all our people." On December 17th Professor Kendall gave an address at a conversazione held at the University on the contributions of Leeds University to scientific knowledge. The Lord Mayor and the City Council paid an official visit to the University on December 18th, and a comic opera, written by Professor Gustang, was performed in the evening. Representatives of county and county borough councils paid an official visit on December 19th, and in the evening a dinner was held by the Old Students' Association. On December 20th the various departments of the University were thrown open to the public for inspection.

SHEFFIELD ANNUAL MEDICAL DINNER

The annual Sheffield medical dinner was held on December 11th, under the joint auspices of the Sheffield Division of the British Medical Association, the Medical Faculty of the University, the Sheffield Medico-Chirurgical Society, and the Local Medical and Panel Committees. Mr Garrick Wilson, chairman of the Sheffield Division, was in the chair, and Dr H B Brackenbury, the Chairman of the Representative Body of the British Medical Association, was the guest of honour. Professor A J Hall proposed the toast of "The Corporation and City of Sheffield," and the Lord Mayor replied. The Master Cutler, proposing the toast of "The medical profession," said that the city ought to be very proud of its doctors, since among the seventeen largest towns in this country only four had a lower death rate than Sheffield. Dr Brackenbury, replying to this toast, drew attention to the relations of medicine to industry, which year by year were becoming more clearly important. He referred to the schemes for industrial welfare, which depended so largely upon medical co-operation, to the subjects of industrial disease and hygiene, and to the recent psychological inquiries, which were of such value in promoting the efficiency of the workers. The development of the whole personality to its highest capacity was the aim of the medical profession, which tended the mind as well as the body. The health of the community was, however, the responsibility, not of the medical profession, but of the community itself, the individuals of which had in their own hands the ruling of their own health. The real function of the medical profession was to teach, to advise, and to help.

PROFESSOR KENWOOD'S VALEDICTORY

About sixty of his former students gathered at dinner on December 19th to bid farewell to Professor H R Kenwood, C.M.G., who is resigning the Chair of Hygiene and Public Health in the University of London. Major-General Sir Wilfred Beveridge presided, and spoke of the esteem which Professor Kenwood had enjoyed during his thirty five years in a teaching capacity at University College. He had proved to be not only a brilliant instructor and an acute observer, but also a real friend to those who studied under him, and his interest in his pupils did not cease after they had passed from his tuition. He had achieved fame, not only in the laboratory and lecture theatre, but in the field of administration and for his invaluable services in military hygiene during the war he was mentioned in dispatches. Dr Louis Parkes, as an old collaborator with Professor Kenwood, joined in the tribute. It was in 1887 that he himself went to University College to assist Professor Corfield, and two years later Henry Kenwood came as one of the students. The speaker was attracted at once by his evident ability and not less by his very engaging manners, which remained one of his characteristics to this day. Kenwood soon found a place on the teaching staff, and both as assistant and as professor he had proved himself a national asset. He had been the means of instructing in Public Health 1,200 men who had taken the diploma and were now scattered over the United Kingdom, the Dominions, India, and foreign countries. He had given them a good foundation of knowledge in all the various problems connected with this large and ever enlarging subject, and now, when medical officers who had taken the D.P.H. in London met one another abroad, the fact that they had studied under this human and accessible teacher furnished an immediate bond of fellowship. Professor

Kenwood expressed his thanks for the overwhelming kindness shown him He had always felt that at University College the teaching was the great end to be pursued, research was dependent upon teaching for there could be no good research without good teaching The record of research at University College was one of which no one need be ashamed and quite early in his professorship methods of research were adopted which had proved of considerable value in public health work At the same time, a great deal of research had the result of leading a man up in his preoccupations and causing him to neglect his teaching Research was far more absorbing than lecturing, and it was really a self sacrificing individual with a keen sense of duty who concentrated on the teaching side in a university chair University College during the last twenty years had been the largest training centre for students for the D P H in Great Britain There had been times when students had to be turned away owing to lack of accommodation He had been singularly fortunate alike in the readiness of his pupils to learn and the loyalty of his teaching colleagues He deplored that on the chemical side the provision at University College was not what it should be, but here again it was an object lesson of what good work could be done in poor circumstances He added that University College had decided to give him an emeritus professorship, and that the department would remain in the very capable hands of Dr Delafield the present lecturer who had been associated with him for the last five years Dr Delafield would keep the flag flying until the time came *for the department to close down for it was extremely* probable that, when the London School of Hygiene opened the post-graduate teaching at University College would cease, and the London School would become the one centre for public health teaching in the metropolis During the evening Professor Kenwood was presented with a silver rose bowl, and Mrs Kenwood with a boudoir clock

Blackburn and District Medical Society

The annual dinner of the Blackburn and District Medical Society was held on December 11th The President Dr J E Bowes, responding to the toast of his health referred to the great desire in the medical profession to-day to take advantage of every possible means to eradicate and prevent disease Already typhoid fever had been nearly banished and good progress had been made in other directions There was still much to do in the work of abolishing tuberculosis and this ideal would come nearer of realization when local authorities used all the powers they possessed He remarked that the regional incidence of pneumonia was very striking the number of deaths from it in the north western division of England was five times that of the southern counties and twice that of London Active research work with regard to cancer was in progress and he believed that there would have to be an alteration of dietary *in the direction of simplification The amount* spent so far upon the investigation of cancer in this country was not more than £200 000, though £8 000 000 was spent on the construction of one battleship In conclusion Dr Bowes appealed for support for the Royal Medical Benevolent Fund The Mayor of Blackburn responding to the toast of "The town and trade of Blackburn" said there was no section of the community who more fully exhibited the true civic spirit than medical practitioners He referred to the fine work of the Royal Infirmary and the great benefits that Blackburn people had derived from it

Bristol Medical School

At the annual dinner of past and present students of the Bristol Medical School, Mr W Ernest Miles I R C S was the guest of the evening, and proposed the toast of "The Medical School" He paid tribute to the past distinguished teachers in both surgery and medicine recalling the names of Professors Greig Smith and James Swayne and Dr Michell Clarke He alluded to the great traditions of which the school was justly proud and added that with its *present distinguished teachers the school could look* forward with every confidence to continued progress in the future Surgeon Commander Blatchford and Mr J J Hughes responded to the toast Musical items were supplied by the jazz band of the Faculty of Medicine, and the guests were subsequently entertained at the University by the wives of the staff of the Faculty of Medicine

Scotland.

Edinburgh Medical Graduation and Reception

At a graduation ceremony held in the M'Ewan Hall of the University of Edinburgh on December 19th, nine-one graduands received the degrees of M B, Ch B The Edinburgh and Leith Division of the British Medical Association, according to the custom which has prevailed for some years, held a reception for those about to qualify in the hall of the University Union on Tuesday, December 16th About sixty of the graduands accepted the invitation and were received by some sixty members of the Association and their wives The entertainment provided consisted in part of addresses varied by musical items After tea the Women *Students' Orchestra, under the direction of Miss McKay* rendered several pieces, Mr Bryan Williams contributed several pianoforte solos, and Dr Allison Lang Dr Keppie Pater on Chairman of the Edinburgh and Leith Division, who presided and received the guests, introduced Mr Alexander Miles, F R C S, senior surgeon to the Royal Infirmary and stated that this was probably the last occasion on which Mr Miles would address them as a teacher, because he was retiring from the service of the Infirmary early next year Mr Miles delivered an address tinged with a happy humour, upon the privileges and responsibilities of medical practice He said that his hearers approaching graduation was similar to a wedding but a wedding from which there was no divorce because once a graduate always a graduate A medical diploma differed from diplomas in other faculties, because it not only conferred an academic distinction, but it carried with it the immediate privilege of earning a livelihood He urged upon them specially the desirability of taking up some hobby distinct from their professional work which would be a relaxation from their labours and would enable these to be carried out with greater zest during working hours The chairman in thanking Mr Miles took the opportunity to urge upon his hearers the advantages to be derived from solidarity of the medical profession which could be largely gained by joining the British Medical Association which included about 70 per cent of the practitioners in Great Britain He also urged upon them the desirability of keeping themselves in touch with periodical medical literature as well as with the results of research *this could be obtained nowhere better than* in the British Medical Journal He also referred to the desirability of every practitioner being a member of some medical defence association for his individual security Mr McCracken one of the graduand proposed a hearty vote of thanks to the chairman and to the Association for the welcome to the ranks of the profession which had been extended to the graduands

Edinburgh Royal Infirmary Radiology Department

Reference was made in our issues of August 23rd and December 6th to the forthcoming radiological department of the Edinburgh Royal Infirmary The plans for this were passed at the Edinburgh Dean of Guild Court last week, and the department is expected to be the largest and most complete ly equipped in this country It is hoped that it will be in working order by October, 1925, and that it will meet the requirements of the Infirmary for many years to come The building is expected to cost £40 000, while the electrical and other equipment will necessitate a further expenditure of £12 000 The building will be situated to the north of the east *clinical theatre and immediately* to the east of the long corridor connecting the surgical and medical houses and will have two floors, with a large basement in which the heavier pieces of generating apparatus will be housed The ground floor will be arranged for radiography, with a large radiographic room for photographing bones and joints a screening room specially designed for following up opaque meals through the stomach

and intestines, another screening room for heart and lung cases, developing rooms and rooms for superficial x-ray treatment and for deep therapy The deep-therapy room will be used chiefly in the treatment of cancer, and it is intended that the apparatus to be installed for this purpose shall have great power and work at a voltage of 250,000 On the ground floor there will be a demonstration room for students, capable of seating 100, and a smaller room, capable of holding 20 to 30 students, also a laboratory for research work, administrative rooms, and waiting and dressing rooms On the upper floor there will be rooms for massage, remedial exercises, and treatment by electrical applications, radium, and artificial sunlight, as well as photographic and developing rooms A very complete system of artificial ventilation by mechanical suction will be installed, and the building will be heated by steam

LEITH WAR MEMORIAL HOSPITAL WING

The managers of Leith Hospital were entertained by the president of the board, Mr John A Lindsay, to luncheon on December 11th The chairman, replying to the toast of the hospital, intimated that the £54,000 which had been subscribed for the addition of a children's wing to the hospital as a war memorial for Leith had been increased by interest to the sum of £63,000 For further alterations on the present building a sum of £5,000 would be required, and of this £2,000 had been already promised The Principal of the University, who was one of the guests, in commenting upon these gifts, said that the fact that hospitals were able to carry on their work on a purely voluntary basis was a tribute to the practical Christianity of the people, and was an example of what might be called the best kind of socialism

APPEAL FOR GLASGOW SICK CHILDREN'S HOSPITAL

The directors of the Royal Hospital for Sick Children in Glasgow have issued an appeal, signed by the Duchess of York, Princess Louise, and other patronesses and patrons, for support, with a view to additions and extensions of the hospital The sum required is £75,000, and in an appeal for this sum the directors set forth the reasons for which they find it necessary to proceed with additions which will complete the original plan, and also with various extensions which are urgently required for the efficient carrying on of the work of the hospital It is pointed out that the whole sum is not required immediately, and that subscribers may make payments of contributions by instalments

Correspondence.

THE NURSING DIFFICULTY IN THE SMALLER HOSPITALS

SIR,—I wish to call attention to a serious difficulty which will shortly have to be faced if the smaller hospitals are not to be deprived of competent nurses The regulations of the General Nursing Council which came into force last July, admirable as no doubt they are for raising the standard, and in consequence the value, of the future nurse, are having certain serious repercussions which have not perhaps yet been fully realized

By practically confining the training of registrable nurses, even in the earlier stages, to the larger hospitals the Council has dealt a blow at the smaller hospitals which must make the satisfactory nursing of them almost impossible No woman who intends to make the profession of nursing the serious work of her life (and no others are likely to make satisfactory nurses) is likely to begin her training at one of the smaller hospitals From the point of view of qualifying for the *Nursing Register* time spent in this way would simply be time wasted The consequence will be that the matrons of these smaller hospitals will find it impossible to obtain the right stamp of probationer, and the nursing of patients in other than the larger hospitals will become increasingly unsatisfactory This is a most unfortunate effect, especially as it is in such hospitals, in which there is no resident house-surgeon, that the of skilled and reliable nurses is most needed

But there are other unfortunate consequences The demand for well trained nurses is increasing, and it will be quite impossible for the larger hospitals alone to meet this demand, especially with the longer and more strenuous course of training now enforced Many of the most satisfactory nurses now employed throughout the country have been trained, and well trained, at these smaller hospitals, and from now onward that large source of supply will cease Indeed, these hospitals, so far from supplying trained nurses, will in the future have to draw upon the larger hospitals if they are to carry on at all, and thus still further deplete the supply of trained nurses, which is already inadequate Surely some way can be found by which the opportunities for training of nurses afforded by the smaller hospitals can be utilized and not wasted

If the General Nursing Council would work out a plan by which the smaller hospitals and certain special hospitals could contribute their share in the work of training nurses and thus form part of a really comprehensive and national scheme, they would go far to overcome the difficulties which I have mentioned This might be done either by grouping the smaller hospitals in convenient areas, or by their affiliation, where possible, with a large teaching hospital, or by a combination of both methods

In any case there is urgent need for the General Nursing Council to come to the aid of the smaller provincial hospitals —I am, etc,

E N NIXON,
Surgeon to the General Hospital, Nuneaton.

December 15th

THE GENERAL PRACTITIONER AND THE MATERNITY SERVICE

SIR,—Judging by your leading article on this subject in the issue of November 15th, you were concerned at the apparent apathy of the general practitioner, and by the fact that he was less articulate than usual Do you not think that he has somewhat changed in this latter direction of late years, and for the better, and that the change is due to his weariness with the more or less constant demands for a higher and still higher standard, verging on the impossible, in every branch of his work, and added to this the frequent complaints and threats which even the most conscientious panel practitioner cannot hope to avoid? From being ultra-sensitive he has developed a protective thickening of skin, and is not so quick to rush into print when reflections are cast on his skill or benevolence

I have reason to believe that the general practitioner, as never before, is anxious to do his duty by his patients in this very matter, that his sense of responsibility is great, and that he gives a deal of thought to this problem In our present state of knowledge it is wrong to put down all or nearly all cases of puerperal infection to insufficient care on the part of the doctor or midwife at the confinement The environment is often to blame The problem will need a somewhat different solution in the case of large populous centres (with their ante-natal and maternity departments under obstetricians who have at their back laboratories where bacteriological and chemical investigations can be made at once) from what it will require in the country districts The matter will be much more easily dealt with in the former case than in the latter, but, as my life has been spent in the country, I shall confine my remarks to it I may, however, interject that the training given to students in obstetrics about thirty years ago was very insufficient, and I believe that it is still, in the main, insufficient It still seems to be the Cinderella of the medical curriculum

In the country the most important thing is to have a complete network of district nurses of a good class and well trained in ante-natal care and midwifery There are still too many gaps in the countryside without a nurse, and in many cases the districts are too large I consider that the services of a doctor are quite unnecessary in the majority of multiparae, but that the nurse must be able to rely on the immediate help of a doctor when she needs one In most ordinary cases patience is the one thing needed, and the nurse has more of this than the doctor, and has also the time, which the doctor has not There are no statistics available, but there can be little doubt that

forceps cases are only a fraction of what they were twenty years ago, when most cases had to be attended by a doctor.

Next in importance is the provision of a maternity ward, however small, in the hospitals of the small towns all over the country. A parturient woman is the most unwelcome patient that can be sent into one of these hospitals at the present time.

Isolated doctors still struggle single-handed on some times with the aid of a colleague fetched from a long distance, with cases of placenta praevia accidental haemorrhage, transverse and breech presentations in the most insanitary surroundings, without even a minute of such common conveniences as a moderately decent lamp or a sufficient supply of clean hot water. Were these same doctors to meet an equally dangerous and urgent case of any other condition calling for surgical intervention, they would send it at once in an ambulance or covered car to hospital. They would gladly do this for the labour case but they know he would not be welcome because no provision is made for such in the average small hospital. I can recall several cases where immediate removal to hospital would almost certainly have saved the mother's life. There is one maternal death for every 240 births and the number of six to eight children (a usual family in the country) means a risk of about 1 in 40 to 1 in 30 in fulfilling her duties, yet there is little or no hospital provision made for her should he develop any of these grave ante-natal risks.

All acute abdominal emergencies are instantly sent to hospital, even when the trouble is in a woman of the child-bearing age and due to gonococcal infection. All these are rightly sent in for immediate surgical treatment under the best conditions, but there appear to be no provisions for dealing similarly with the decent wife of a labourer in the country who may have developed an equally grave condition in her confinement.

From the hospital's side it is mainly or altogether a matter of finance, as in most cases it would mean some extra building. Otherwise the expense would not be great for the matron or one staff nurse could have the certificate of the Central Midwives Board in addition to the usual qualifications.—I am, etc.,

Shaftesbury Dorset Dec. 8th. T. MACCARTHY.

TONSILLECTOMY

SIR,—The aim of the surgeon at the present time is to remove the tonsil of the child as completely and as cleanly as possible with the least trauma to the patient from the anaesthetic and from subsequent sepsis and scarring, and with the minimum loss of blood. Mr. T. B. Layton's opinion is that this can be done by the guillotine only. If that is so then some good reason must be found why our laryngologists have partially or wholly abandoned the guillotine in favour of dissection. One cannot imagine that they have failed to master the manipulations of the guillotine, and therefore have resorted to the more difficult operation of enucleation by dissection.

Further if these results from dissection are such as Mr. Layton describes surely common sense alone would have led them to give it up.

Still they continue to enucleate by dissection. Why is it? Because dissection in skilled hands prevents bleeding without any added risk to the patient whilst the guillotine causes useless loss of blood. The whole idea of dissection is, I understand, it is to clamp and tie the main blood vessel to the tonsil as the operation progresses so that the only haemorrhage is from the capillaries of the capsule as it is scratched through with a fine toothed dissecting forceps. Therefore I cannot understand Mr. Layton's statement that there is more haemorrhage in dissection unless he means in unskilled hands, when anything is possible.

To my mind the whole question turns on whether haemorrhage is to be allowed to continue till it ceases of its own accord or whether it is to be prevented by pressure on the tonsil bed or by ligature of vessels. If the haemorrhage is of no importance then enucleation by the guillotine under ethyl chloride, skilfully administered, is the operation of choice. A small piece of tonsil may occasionally be left, but as a rule it causes no trouble, at least at the time. If on the other hand, complete enucleation is desired with practically no bleeding, then there is but one method, and that is dissection with ligature of the vessels under oxygen and ether anaesthesia.

In skilled hands there need be no septic after-complications and no cutting, and no more risk from the anaesthetic than in any other operation. The application of pressure to stop bleeding after removal by the guillotine is uncertain in its results and however dry the tonsil bed may appear before the patient leaves the table, cases occasionally arise where haemorrhage has recurred—or, to be more correct, has continued—and the only evidence may be pallor followed by vomiting of a large amount of bright red blood. Then comes the question of how to stop it. Children bitterly resent the application of a tonsil clamp and the introduction of sutures through the pillars and bed of the tonsil is a most painful procedure without an anaesthetic, and scarring almost certainly results. We are therefore left with the alternative of a second anaesthetic in a child already suffering from shock and ligature of the bleeding point, which would have been done at the time if dissection had been employed.

Even if none of these treatments have been necessary and the bleeding has ceased on propping up the patient, the child takes some time to get over the loss of blood and cases have occurred where the effects have been very serious. I have kept a record of the blood lost in many hundreds of cases of enucleation by the guillotine, and in some of them the quantity has appalled me. I am sure that many do not realize the amount that is lost.

Of course, the technique of dissection is more difficult to acquire, much practice is necessary to learn to ligature the vessels rapidly, and here the skilled help of a regular assistant is invaluable. A highly skilled anaesthetist is essential, but he may at the same time act as assistant.

Everyone admits that the tonsillotomy or pre-enucleation days was very successful so far as we know, and that the more expert the surgeon the more tonsillar tissue he removed. In those days the aim was to remove as much of the tonsil as possible for the same reason as we enucleate now, because the extent of the disease could not be diagnosed before operation then any more than it can now.

It is sometimes difficult to decide that the tonsil is diseased. I venture to prophesy that the unnecessary waste of blood by the guillotine method will be the direct cause of dissection being generally adopted by the laryngologists of the next generation.—I am, etc.,

Nottingham Dec. 11th. H. BELL TAWSE.

SIR,—Before this correspondence ceases may I emphasize three points?

1. The great advance in guillotine technique during this past decade owing to the development of the 'reverse' method. Many people in discussing the value of the guillotine base their opinion on their recollection of guillotine operations in pre-war times when the percentage of tonsils cleanly enucleated by this method was under 50. Sluder now claims 99·6 per cent. of complete enucleations for this method—"after real skill has been acquired"—and he is not far wrong. Certainly the percentage of children's tonsils should be 99 and not far short of that for adults.

2. The necessity for practice in acquiring skill with the guillotine. It is like learning golf. No matter how good an athlete a man may be he must practise the golf swing over and over again. He must take out his club and half a dozen balls and play his shot over and over again. After many months he gradually develops the knack of hitting the ball cleanly every time. When he has learned to play a good game he can keep it up with occasional practice. So with the guillotine—repeated practice is necessary in the beginning. The operator must repeat the movement hundreds of times on all types of tonsil before real skill is achieved. Skill in dissection of tonsils is more rapidly gained than skill with the guillotine.

3. The modern guillotine method is that of Whillis and Pybus. The use of the finger to evert the tonsil into the ring of the guillotine was the kernel of their paper published in 1910, and it is the kernel of guillotine enucleation to-day. The essential feature of Sluder's method, as

described in his paper published in 1911, was the use of the "alveolar eminence on the mandible to stuff the tonsil through the ring" The use of the finger is alluded to only as a secondary procedure recommended for occasional use in dealing with flat fibrous tonsils In his latest book (1923) Sluder recommends the use of finger eversion in *all* cases Although the American school deserves great credit for developing and popularizing the reverse method of tonsillectomy, let us render honour where honour is due and call the method by the names of Whillis and Pybus of Newcastle —I am, etc,

Guildford, Dec 14th T B JOBSON

THE DIAGNOSIS OF PNEUMONIC PLAGUE

SIR,—The importance of establishing the diagnosis between plague complicated with pneumonia and pneumonic plague can hardly be exaggerated from the point of view of the medical men and the nurses attending the case, yet it seems to be far from easy Medical textbooks for the most part fight shy of the point, and content themselves with the remark that pneumonic plague is peculiarly fatal to those in attendance Indeed, they leave one to suppose that until a doctor or a nurse dies one has really no right to make a diagnosis of pneumonic plague Yet these latter would prefer to have the diagnosis established before their own death, and it is in these circumstances that I am writing to inquire of your numerous readers whether it is possible to make a diagnosis in a given case

Manson's *Tropical Diseases* gives no help Stitt thinks that plague complicated with pneumonia is the origin of, if not identical with, pneumonic plague Wu Lien Teh, writing in the *Practice of Medicine in the Tropics*, says the diagnosis is usually clear from the bacteriological examination of the sputum, in which the bacillus is found in enormous numbers and in almost pure culture If one accepts his method of diagnosis, then indeed bubonic plague complicated with pneumonia or vice versa is indistinguishable from pneumonic plague in a large number of cases

What of the cases of plague in which a bubo is the only outward and visible sign of the disease, but in which a lung puncture or *post mortem* lung smear shows *B pestis* in pure culture? What, too, of those cases without buboes in which no physical signs are present in the chest until just before death, but in which *B pestis* is found in the blood in life and consolidation, slight or gross, is found after death and a lung smear gives a pure culture of the bacillus? It is true one can take refuge in a terminological harbour and apply the word "septicaemic" to both these cases, but this hardly advances us along the line of discovering wherein they differ from pneumonic plague—so called No one as yet has denied the existence of *B pestis* in the blood in pneumonic plague, and for my part I cannot conceive of pneumonic plague being other than septicaemic in its final stage

A point of close resemblance between plague-cum-pneumonia and the pneumonic plague of the textbooks seems to be that both are absolutely and equally fatal The first sign of chest trouble in a case of mild bubonic plague appears to be comparable with the death token of the Middle Ages At least the result is the same—I am, etc,

Lagos, Nigeria, Oct 24th N A DYCE SHARP,
West African Medical Staff

TREATMENT OF GOITRE BY IODINE

SIR,—Dr Joseph's communication (November 22nd, p 975) on the treatment of goitre by iodine is interesting I am sorry he has not given the minor details and precautions that he says are necessary for success This subject is far from clear and details may prove to be of the utmost importance I can add my testimony to the success of syrup of the iodide of iron in these cases This is a most useful drug in other cases too It is most valuable in enlarged glands of the neck Does the iodine stimulate the thyroid—the defensive gland of the body—and thus cause the enlarged cervical glands to disappear? I feel sure if this preparation was more frequently used there would be fewer tuberculous glands of the neck

Cases of simple goitre are, I am sure, an enlargement of the gland to supply more iodine for the requirements of the body From these two classes of cases iodine would appear to act in a double way it seems to stimulate the thyroid, and also to supply the iodine that is deficient I believe we have in nux vomica a drug that stimulates the suprarenals

In giving syrup of the iodide of iron to children many years ago I was struck by the remark so often made by the mothers that the child's appetite was much improved Other medical men whom I spoke to also tried it in pale children with loss of appetite, and it proved successful in their hands Later I came to the conclusion that these were cases of subthyroidism, and after the course of the syrup they got a good appetite, put on flesh, and had a healthy appearance The failure of the syrup in Graves's disease is what one would expect It is a different disease—sympathetic in origin—and not due to iodine insufficiency

People living in the same district, eating the same food, and drinking the same water do not all develop goitre Is it that some people require more iodine than normal people? It cannot be that they have not the power to assimilate it, for when given in the syrup of the iodide of iron they get better

We get the physiological enlargement in young girls about the age of 14 years Is more iodine required then, and, if so, why? Why also do we see it so seldom in the male sex? In treatment I would advise the giving of very small doses —I am, etc,

Southsea, Nov 24th D MCASKIE, M B

EXERCISES FOR THE PELVIC FLOOR MUSCLES IN DYSCHEZIA AND PROLAPSE

SIR,—The interesting and instructive paper with cases by Dr Stacey Wilson on the cure of uterine prolapse by re-education of the muscles constricting the vagina (December 6th, p 1041) indicates completely the conception of the necessity for and the sufficiency of the pelvic floor muscles for the pelvic visceral retention For although Dr Wilson refers to the muscles, the disability of which is the predisposing cause of uterine prolapse, as "vaginal" muscles, and speaks of the "vaginal sphincter" in this respect, it is quite clear that it is not the "constrictor cunni" but the levatores ani which are affected by the exercises The muscular compression exerted upon the fingers when during vaginal examination the patient, in response to a request, contracts the parts is due to a contraction of the levator ani muscles, especially of their medial parts, which form the postero-lateral parts of the pelvic floor aperture through which both the vagina and rectum pass to quit the pelvis This important part of the levatores ani, known as the pubo-rectalis, was called by Holl the sphincter recti, from its effect on the rectum Passing from the pubes by the sides of the vagina to behind the anal canal, where the belly of one side runs into that of the other without intermediate tendon and without attachment to the ano-coccygeal raphe or the coccyx, on contraction it compresses the anal canal against the pubic arch, and in doing so necessarily compresses the vagina at this level which is placed in between Thus, Dr Stacey Wilson tells us that the voluntary contraction of these "vaginal" muscles, instrumental in the retention of the uterus, is induced by asking the patient to tighten herself up "as if she were endeavouring to control a sudden attack of diarrhoea"

Of course, with such a movement, the sphincter vaginae (that is, the constrictor cunni), when intact, is probably involved, but this movement occurs even in cases of complete rupture of the perineum—that is, in cases in which the two halves of the constrictor cunni are separated from each other posteriorly, and in consequence of which their effect on the vulva as a constrictor must be absent or negligible Dr Wilson has shown that even in such cases as the result of the exercise of frequently tightening herself up—in the beginning "many times during every hour of the day"—the patient "may nevertheless be able to maintain her uterus (previously extruded) in its normal position without the need for a pessary"

Not only do the cases Dr Wilson cites support this conception, but the remarks of Dr Arthur Hurst and of Dr A Adams (in your issue of December 13th p 1136) also do so Dr Hurst mentions a case of rectal prolapse treated successfully in this way Dr Adams refers to the "undue passivity" of many women in regard to their sexual feelings" Dickinson long ago stated that the levator ani is especially well developed in erotic women and that the muscle is in a better state than normal in cases of bowel incontinence from complete perineal laceration is an observation which can be made every day Women of the former type actively participate during coitus during which in the normal the levator ani muscles of the woman grasp the organ of the male That in cases of complete perineal tear the levator should be in constant use is intelligible from the effect of the lesion of the bowel These women are constantly tightening them selves up to prevent the unexpected escape of gas and even of faecal material

But there is another point which should not be missed Important as the levator ani muscles are in the matter of the pelvic viscera retention they are even more important in virtue of their effect on the body as a whole Thus Dr Wilson, in the notes of his first case state that with the local improvement the patient's general health also greatly improved" This simple statement requires elucidation It is true that when the pelvic floor muscles are efficient they prevent extrusion of the pelvic viscera but they do much more than this By preventing the escape of visceral parts they enable the pressure within the pelvis and abdomen, in virtue of which the parts tend to escape to be increased as it is in the normal during activity Without great rises of the intra abdominal pressure great activity is not possible Conversely they allow and even participate in determining a good average pressure during resting states Clearly the condition of the body during rest is related to and corresponds with the degree of potential activity

When the relation of the intra abdominal pressure to general metabolism is realized when it is recognized that this pressure is basal in the adequate return of blood per unit of time *to* the heart and that on this (for one thing) the aortic blood pressure—and so the blood flow through every organ—depends much may happen I prophesy a revolution in medical thought I see on the one hand that neurasthenia (in which the intra abdominal pressure is reduced), and on the other that eclampsia (in which the intra abdominal pressure is increased) and perhaps that many other internal disorders (for example acute nephritis and even convulsions in children) will be understood and that the neglected levator muscle will be acclaimed as playing an essential part in many vital processes—I am, etc,

WET WINDS AND EARLY PHTHISIS

SIR,—In reply to Dr Ward's letter (December 13th, p 1140)

1 I have framed no "hypothesis" Anyone who has followed my work with reasonable care will have noticed how scrupulously I have avoided doing so I have simply examined statistics and recorded conclusions

2 To Torquay Dr Ward does grave injustice Much of it is sheltered from westerly winds and I have a high opinion of its value

3 When Dr Ward describes my statistics as 'malleable' he displays a remarkable want of attention in his reading The most outstanding fact about these statistics is the apparent unavoidability of the conclusions I have drawn

4 Dr Ward's criticism of my able collaborators seems *une mauvaise plaisanterie*

5 I have laid down no 'axiom' My conclusions as to limits of shelter are plain deductions from my material

6 In the very paper we are discussing I have thankfully acknowledged the great help afforded me by Dr Brownlee's independent investigation in 1920 in the districts of Barnstaple and Okehampton, and lately by the independent investigations in West Shropshire by Dr A C Watkin and in Derbyshire by the medical superintendent of the County Sanatorium Independent inquiry is what I have always desired Independent inquiry is what I am now asking for all over the country May one hope that it may be undertaken soon and widely?—I am, etc,

Exeter Dec 15th W GORDON

THE LATE PROFESSOR J I HUNTER

SIR,—I should be very grateful if you would correct certain errors which through my own carelessness, were made in the obituary notice of Professor John Irvine Hunter

The name of the journal in which the Murphy Oration is being published (see reference on page 1183 at the top of the first column) should be *Surgery Gynecology and Obstetrics* The date of Professor Hunter's departure from Sydney (see page 1181 at the bottom of the second column) should be August 1921 and of his return February, 1923—I am etc

London Dec 18th G E S

Medico-Legal.

A CHARGE OF SEDUCTION DISMISSED

At the Birmingham Assizes on December 16th a special jury dismissed a claim brought by Mr Thomas Morley of Saltley against Mr R M Pardhy F P C S of Newhall Street, Birmingham for damages for the alleged seduction of his daughter, Mary Margaret Morley aged 19 Mr Justice Lush, in the course of the hearing raised the point as to whether an action for damages could be brought for what was after all, the felony of rape without first vindicating justice by a prosecution for rape Mr Vachell K C who appeared for the defendant said he had not raised the point because Mr Pardhy did not desire to shelter himself behind anything that savoured of a technicality

The plaintiff's daughter in her evidence said that on February 20th 1923 she went with her mother to the Homoeopathic Hospital Birmingham for treatment They waited two hours and at about 2.50 p m they were shown into a room where the defendant was alone After a conversation they were told to go to the other side of a heavy green curtain reaching to the floor which divided the room There the witness partly undressed and after an examination which took place while she was on a table her mother was told by the defendant to go to the other side of the curtain After her mother left the room the witness was told to leave the table and she was provided with a stool to lean over A blanket was placed over her shoulders A little later the defendant washed his hands and she was given a card to go to the dispensary She did not know anything was wrong until she gave birth to a child on November 10th 1923 she was working at a factory on November 9th

The plaintiff's wife in her evidence said she accompanied her daughter to the hospital on February 20th 1923 After the examination of her daughter had proceeded for a little while the defendant asked her to go and sit down There was only one chair and that was on the other side of the curtain which divided the room and the witness went there She sat there reading a book and heard nothing at all to arouse her suspicions that there was anything going on She at there for ten minutes to a quarter of an hour and then the defendant came out and asked her a question about certain marks on her daughter's neck and forearm Then the defendant asked her to help her daughter dress and witness did so

Dr W T James of Bordesley Green gave evidence of the confinement and said he thought the baby was an Oriental—not a Japanese not a Chinese not a negro Witness had a conversation with the mother and then saw the defendant who looked flabbergasted when he heard the suggestion that he was the father The birth of the baby was consistent with intercourse having taken place on the date of the girl visit to the hospital but equally so with intercourse having taken place in the last week in January (when the girl was on holiday at Weston-super Mare)

Mr Vachell opening the case for the defence said Mr Pardhy was a well born native of India a Brahmin His father was a celebrated Indian judge He came to this country somewhere about 1900 having previously served for a short time in the medical service in the South African war Here he became a Fellow of the Royal College of Surgeons and L P C P He was 30 years of age and had married a lady who stood fast by his side in the case In 1910 he became surgeon to the Birmingham and Midland Homoeopathic Hospital a post he had held ever since Throughout the whole of 1923 he was on two days a week seeing out patients in the afternoons it being quite usual to him to see from eighty to ninety patients in one afternoon No one but a lunatic would have attempted to do what it was alleged the defendant did in the teeth of almost certain detection

Mr Pardhy in evidence said he had no personal recollection of the girl's visit—he saw thousands of persons—but he found notes of the case he had made in the register he kept The mode of examination he adopted he had practised for the last twenty years,

and it was a well recognized method for cases of that sort During his work he was liable to interruption Colleagues from the next room came in frequently to ask his opinion about a case The matron, or nurses, might come in, the house surgeon might come in Messages were brought in, and there were telephone calls to be answered The curtain was not a thick one At that hospital no nurse was ever present during the examination of out patients

Cross examined he did not recollect but if he did ask the mother to sit down on the other side of the curtain she must have been in his way He had employed private inquiry agents, but they had not been able to find any coloured person, other than himself, with whom the girl had had anything to do

Dr Thomas Wilson professor of midwifery and diseases of women, Birmingham University said the procedure used by the defendant appeared to him to be in accordance with the routine and custom of the special branch of the profession to which he (the witness) belonged If the allegation were true he could not conceive of the mother not knowing what was happening for the girl not to know was not impossible, but seemed incredible

Mr Justice Lush, summing up directed the jury's attention to three remarkable things first, it was a part of the plaintiff's case that an educated, clever man who would know what he was doing and the risks he ran, was willing in order to gratify his lust, to commit this wicked crime on a young girl while her mother sat about two or three feet away with nothing dividing them but a curtain, and when a single word or cry would have brought her to the girl's side, secondly, that the girl who was said to have been treated in that way never imagined for nine months that the doctor had had relations with her thirdly that the girl, having become pregnant, went right down almost to the moment of child birth without having the slightest idea that anything unusual in a physical sense had happened to her

The jury, who had viewed the consulting room at the hospital where the intercourse was alleged to have taken place and who had been shown the baby returned a verdict for the defendant, Mr Justice Lush observing "I think it is right to say that I quite agree with your verdict"

Messrs Le Brasseur and Oakley, solicitors for the defence were instructed by the London and Counties Medical Protection Society

UNIVERSITY OF LONDON

THE PARLIAMENTARY ELECTION

DR F G LITTLE was entertained at dinner on December 16th by the University of London Graduates' Association to congratulate him on his election as parliamentary representative of the University Sir W J Collins, the founder of the association, who was in the chair, presented Dr Little, on behalf of the association, with an illuminated address in commemoration of his election, "irrespective of party politics and in vindication of the policy of the University of London Graduates' Association, for the maintenance and development alike of the teaching work of the University and its open system of examination, without intervention by external agencies unacquainted with its history and progress" The toast of Dr Little's health was proposed by Captain J A Douglas, chairman of the Association of Parliamentary Election Petitions In his reply Dr Little said that the fight at first had seemed a forlorn hope, but it was an occasion for going on with the twenty year struggle to maintain the principles on which the University was founded Throughout the world and in every profession a large number of men and women cherished the warmest affection for it In response to the toast of the colleges and schools of the University, the Principal of King's College said that neither he nor, so far as he knew, any other principal officer of a college was in favour of the cardinal principle of the Haldane Commission or, indeed, of many of its subsidiary principles would desire to see most of its [illegible] with regard to the position of [illegible] tion of the Senate The health of the chairman was given by Sir William Willcox and suitably acknowledged

Obituary

HERBERT WILLIAMSON, M A, M B, F R C P,

Physician Accoucheur to St Bartholomew's Hospital

HERBERT WILLIAMSON, whose sudden death is so great a loss to the Medical School of St Bartholomew's Hospital, was in his 53rd year He came to London from St John's College Cambridge, and characteristically determined to find out for himself which of the London schools he should join He wandered and inspected several but, as he often has recounted, when he looked through King Henry the Eighth's Gate and saw the fountain the trees and the flowers he felt his search was at an end and he entered the school in which, save for a very brief period of less than a year he always held an honoured place From the first months of his student days his exceptional powers were recognized alike by his teachers and his fellow students The latter never had any doubt but that Williamson was marked out for success in whatever walk of the profession he should find himself He obtained the M R C S and L R C P diplomas in 1896 and the M A M B, and B Ch degrees in 1898 Naturally he was a prizeman, and after holding the post of resident to those brilliant surgeons Buthin and Lockwood, he became resident in the gynaecological wards Sir Francis Champneys and Dr W S A Griffith who were at that time respectively physician accoucheur and assistant physician accoucheur, were quick to recognize his merit and though for a short time there was no opening for Williamson he was remembered when the opening did occur and came home from the South African war where he was serving as a surgeon in the Imperial Yeomanry Hospital, to take up the position of midwifery tutor In that capacity he served the school and the hospital for several years with so marked a success that in 1906 a fresh post was created in the department and William on was elected to the staff of the hospital He had already an extensive private practice and this rapidly grew so that in a few years his opinion and his services were widely in demand He was elected F R C P in 1911 He enjoyed his success, but still more he enjoyed his work He was never so happy as in the service of the hospital and school whether in teaching or working in their interests in other ways Indeed in those years he took too little relaxation from the exactions of his work and outside his regular holidays very rarely spared time for pleasure He was not especially devoted to any form of sport he was not a golfer, and seldom even gave himself a Sunday freedom from work Latterly his summer holidays had been spent in Cornwall and there he had been accustomed to go for long walks His physique was not robust but he very seldom ailed and his temperament was even and judicial He was always the most delightful companion enjoying and telling a good story and his lectures and bedside teaching were *often illuminated by sparkles of wit or humour*

As the years went on he became more and more trusted in the councils of the school and the hospital and it is in that sphere as much as in any other that he will be greatly missed Outside the hospital he had filled many important posts and always with distinction He had always been a good speaker in public but of recent years since the war, had gained a reputation in this respect which in the estimation of good judges, placed him in the front rank His speeches at the octocentenary dinner of St Bartholomew's Hospital in 1923 and at the dinner of the Royal Society of Medicine last year were a delight to those who heard them and made his name familiar to many who had not previously known him

He had not been in the best of health since the summer, but to most of his colleagues there was no sign of failing powers Only to those who were most intimately associated with him in work was there any indication that he was feeling the strain To the rest he appeared to be in full vigour, and his advice and counsel were as ready and judicious as ever given In November he had an attack of influenza and was distinctly pulled down by it He went away for a short time to the seaside and returned apparently fit A few days' work, however was all that was left for him On December 15th he did not feel up to undertaking his usual full day's work and went for a

walk in the Chilterns His dead body was found the next day, and from the evidence he must have suffered from a sudden syncopal attack after climbing a hill

His death leaves a gap in the ranks of gynaecologists, and will be deeply regretted by the many members of the profession to whom he was known, and by hundreds of private patients to whom he was not only a trusted physician but a valued friend To his contemporaries, his colleagues, and the students of St Bartholomew's Hospital, both past and present, there is a deeper sense of loss Not merely have they lost one of the ornaments of the school, but they mourn the decease of a man whose deep love and devotion to his school was requited by a rare sense of personal attachment in all those with whom he mixed in their common life

H T

CLARENCE COOPER, M D, F R C S,

Deputy Surgeon General I M S (ret)

DEPUTY SURGEON-GENERAL CLARENCE COOPER, Madras Medical Service (ret), died at South Norwood Park, London, on December 18th, aged 94 He was born at Brentford, and was the son of George Cooper, F R C S He was educated at Guy's, and took the M R C S and L S A in 1852, and the M D St Andrews in 1853 He became M R C P Lond in 1860 and F R C S Eng in 1867 He entered the Indian Medical Service in November, 1853, seventy-one years ago, attained the rank of brigade surgeon in November, 1879, and retired at the end of 1881, with an honorary step of rank as deputy surgeon-general

He went to Labuan in Borneo in medical charge of troops in 1855, and not long afterwards his services were lent by the Indian Government to the Colonial Office In Labuan he spent nearly ten years, holding many and various appointments in succession colonial surgeon, coroner, police magistrate, superintendent of convicts, Colonial Secretary, judge, and member of the Legislative Council, receiving the thanks of two Secretaries of State for the Colonies, as well as of the Government of Labuan In 1864 he returned to India, and after holding various military posts was, in 1874, appointed principal medical storekeeper at Madras, he held that office till he retired After his retirement he joined the Court of the Society of Apothecaries, and served as Master of the Society in 1903-4 The Army List assigns him no war service He went to India nearly four years before the Mutiny began, but throughout the two years of that campaign he was serving in Labuan, far from India

Since the death of Surgeon-General Sir Benjamin Simpson, in June, 1923, Clarence Cooper had been the senior officer on the retired list of the I M S His successor as the doyen of the Service is Deputy Surgeon-General Philip Warren Sutherland, who joined the Bengal Service in 1854, and is the only surviving member of the I M S who served in the Indian Mutiny

---

DR PERCY WILLIAM SPAULL, who died on December 16th at his residence in West Kensington, was educated at St Thomas's and King's College Hospitals He obtained the diplomas M R C S, L R C P, in 1894, and in 1909 the Diploma of Public Health Dr Spaull was particularly interested in public health administration, and filled the posts of deputy medical officer of health for the metropolitan boroughs of Fulham, Holborn, and the City of Westminster His other appointments included those of assistant medical officer in the Public Health Department of the London County Council and medical officer to the Post Office He was a Fellow of the Society of Medical Officers of Health and lecturer on sanitary law and administration at the Battersea Polytechnic He was chairman, and formerly secretary, of the Chelsea Division of the British Medical Association

---

We regret to record the death of DR GORDON ABERCROMBY LANG in Inverness, at the age of 58 His father, the Rev Gavin Lang, had three brothers, all clergymen of the Church of Scotland, of whom one was Professor Marshall Lang, Principal of Aberdeen University another kinsman is the Archbishop of York Dr Gordon Lang was educated at Aberdeen University, where he graduated M B, C M in 1889 Returning to Inverness he commenced practice, and was appointed to the staff of the Northern Infirmary, holding the post of consulting medical electrologist until the time of his death He was also school medical officer for the mainland of Inverness until a few months ago, when he was compelled by ill health to resign His other appointments included those of medical officer of Forbes Dispensary, Inverness, and house-physician to the Great Northern Central Hospital, London Dr Lang was interested in motoring from its commencement, and was one of the first to use a car in his practice, this car was steam driven In his younger days he was a keen athlete, excelling especially at Rugby football He contributed several papers on hygiene and other subjects to school medical magazines He was for many years a member of the British Medical Association He is survived by his widow and one daughter

---

DR ALAN OSBORNE COURTIS of Oxted died on December 3rd, at the early age of 34, after an operation for appendicitis He was the son of Sir John Courtis of Llandaff, and was educated at Repton, Pembroke College, Cambridge, and St Bartholomew's Hospital He took the diplomas of the English Conjoint Board in 1916 and graduated B Ch Camb in 1921 and M A and M B in 1922 Dr Courtis began practice at Oxted about two years ago in partnership with Dr G D Laing of Limpsfield, and during that period had made a large number of friends He was a member of the Reigate Division of the British Medical Association He is survived by his widow and a young daughter

---

DR JAMES ERNEST DUNBAR, who died at Abertillery on December 7th, from pneumonia, was educated at the London Hospital, and graduated M B, B S Lond in 1906 During the war he served in Palestine and Egypt, and subsequently practised in Wales, eventually settling down about two years ago in Abertillery He was buried at Risca cemetery on December 10th A colleague (D T R) writes His friends knew Dr Dunbar as a man with a very lovable nature, sterling qualities of mind and heart, honesty of purpose, and great natural ability

---

DR JAMES DOOLEY, O B E, formerly of Creswell, died at his home at Knocklong, co Limerick, on December 6th, aged 43 He was educated at the Catholic University, Dublin, and graduated M B, B Ch, B A O, N U I, in 1910 After acting as assistant to Dr Wood of Creswell he subsequently entered into partnership Dr Dooley was keenly interested in local sports and pastimes, and was also medical officer to the Creswell Boys' Brigade On his leaving the village in January last he was presented by the brigade with a gold wristlet watch and by the hockey club with a silver cigarette case During the war he was medical officer of the V A D Hospital at Creswell, for which services he was awarded the O B E

The Services.

DEATHS IN THE SERVICES

Lieut Colonel Joseph Gibson R A M C (ret), died on October 1st aged 68 He was educated at Trinity College, Dublin, where he graduated M B and Ch B in 1878 Entering the army as surgeon on February 5th 1881 he became lieutenant-colonel after twenty years' service and retired on July 15th, 1908 He served in the Burmese campaign in 1885-87, receiving the medal with a clasp and in the South African war in 1900-2, when he took part in operations in the Transvaal and Cape Colony, and received the Queen's medal with three clasps and the King's medal with two clasps

Major Robert Carlyle Carlyle, R A M C, is reported as having been killed in the mutiny of black troops at Khartoum on the evening of November 27th He was born on September 22nd 1887 was educated at Edinburgh, where he graduated M B and Ch B in 1911, and entered the army on July 26th, 1912 He was seconded for service in the Egyptian army on February 10th, 1917, and attained the rank of major on July 27th last

Medical News.

DR CHARLES SANDERS, who recently retired from the post of medical officer of health for the Borough of West Ham, was, on December 11th, presented by the Public Health Department with a handsome framed illuminated address (bearing 116 signatures) and a leather suit case, and by the Schools Medical Service with an inscribed silver plated salver, and entrée dishes Dr F G Collins (medical officer of health) and Dr Sherrett (schools medical officer), who made the presentations, testified to the esteem in which Dr Sanders was held Mrs Sanders was presented with a leather handbag

DR P SMYTHE HICHENS, on the occasion of his retiring from the post of honorary physician to the Northampton General Hospital after twenty three years service, has been presented with his portrait in oils and a cheque on behalf of over eighty subscribers to a public testimonial fund

IN response to an appeal recently made by the chairman of directors of Dundee Royal Infirmary for completing extensions to the Caird Hospital, a sum of £5 000 has been sent by Mrs Marryat, a sister of the late Sir James K Caird, Bt, Dundee who two years ago gave £20 000 for the same department of the infirmary

A SPECIAL number of the *Bruxelles Medical* has been devoted to an account of the proceedings of the annual medical congress known as "Journées medicales de Bruxelles, which was held at Brussels from June 29th to July 2nd

THE annual dinner of the Yorkshire Association of Graduates of the University of Glasgow was held in the Great Northern Hotel, Leeds, on December 5th, when there was present a company of ninety members and friends the President Dr George Hanson (Bradford), in the chair The chief guests were Professor John Glaister and Dr J B Baillie, the recently appointed Vice Chancellor of Leeds University The annual report shows that the association is in a flourishing condition, with a membership of 126 Membership is open to all Glasgow graduates resident in Yorkshire particulars may be obtained from the honorary secretary, Dr William MacAdam, Cromer Hall, Leeds

MR ALLAN WYON, sculptor, has presented to the Leeds University a bronze medallion in memory of his brother the late Dr G A Wyon, formerly lecturer in pathology in the University

SIR ARBUTHNOT LANE will lecture on the treatment of fractures in the West Lecture Hall of the Royal Society of Medicine on January 20th at 5 30 p m The London Temperance Hospital, in association with special hospitals, will hold a two weeks intensive course from January 12th in all the general and special departments of medicine and surgery A special course in cardiology limited to sixteen, has been arranged from January 12th to 23rd at the National Hospital for Diseases of the Heart From January 5th to 31st the Royal Eye Hospital (Southwark) will hold a course in ophthalmology, and there will be a special course in the diagnosis and treatment of common diseases of the nervous system at the West End Hospital for Nervous Diseases Dr Porter Phillips and Dr Thomas Beaton will deliver nine lecture demonstrations on psychological medicine, beginning on January 6th, at the Bethlem Royal Hospital A special course in urology will take place at the St Peter s Hospital for Stone from January 12th to February 7th provided ten entries are received The February courses include diseases of children, dermatology, gynaecology, tropical diseases venereal diseases, and a fortnight s intensive course in medicine, surgery, and the special departments Copies of the syllabus of the e courses may be obtained from the Secretary to the Fellowship of Medicine, 1, Wimpole Street, W 1

A COT in the children s ward at the Victoria Hospital, Cork has been endowed as a lasting tribute to the memory of the late Professor W E Ashley Cummins, honorary physician to the hospital for over thirty years

DR W F COPFIELD (M O H Colchester) has been elected a life Fellow of the Royal Sanitary Institute Dr A A Mussen (M O H Liverpool) has been elected a Fellow

DR G BEFBENEP SCOTT, barrister at law, Middle Temple has been appointed deputy coroner for the Western District of London

A DAILY medical journal entitled *El Dia Medico* which claims to be a medical review of reviews and to be the organ of the medical profession in the daily press, made its first appearance at Barcelona on December 1st The specimen copy which we have received contains abstracts from Spanish and foreign literature university and medical society intelligence, reviews of books, and a recent portrait of Ramon y Cajal

THE Anti Prohibition League held an international congress in London last June It has now issued a report of the proceedings at that congress and the text of the papers read before it The volume, which is an octavo of 156 pages, can, we understand, be obtained (price 5s) from the League at 123, Pall Mall, London, S W 1

A POST GRADUATE course of two years duration has been arranged by Professor Comba at the Pediatric Clinic of Florence to train candidates for the diploma of pediatric specialist which has recently been created in Italy by a royal decree

THE October issue of the *National Medical Journal of China* commemorates the tenth anniversary of the China National Medical Association whose official organ it is During the last ten years the Central Government of Peking has been persuaded to allow the official dissection of cadavers in medical schools, and to recognize, since 1915, Western medicine as the proper standard for medical qualification An effort is now being made to establish a central medical council to control the registration of medical students and practitioners throughout the country A long list of hospitals and medical schools organized includes a chain of antiplague hospitals and research laboratories in Manchuria A strong plea is put forward in the journal for an independent head quarters for the as ociation

PROFESSOR BELGONIE of Bordeaux has been awarded the Grand Cross of the Legion of Honour

DURING the recent war in Chekiang the Hangchow C M S Hospital dispatched a Red Cross unit of twenty three to the Huchow front It is hoped to send eventually four or five such units The hospital is reserving 200 beds for casualties, and for the second time in its existence is acting as a base hospital

THE late Dr Alfred Mantle of Harrogate left estate valued at £36,709, with net personalty £33,525

PROFESSOR JEAN LOUIS FAURE has been elected a member of the Academie de Medecine in the Section of Surgery

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS *forwarded for publication are understood to be offered to the* BRITISH MEDICAL JOURNAL *alone unless the contrary be stated* Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Financial Secretary and Business Manager 429 Strand W C 2 on receipt of proof

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—not necessarily for publication

ALL communications with reference to advertisements as well as orders for copies of the JOURNAL should be addressed to the Financial Secretary and Business Manager 429 Strand London W C 2 Attention to this request will avoid delay Communications with reference to editorial business should be addressed to the Editor BRITISH MEDICAL JOURNAL 429 Strand W C 2

Communications intended for the current issue should be posted so as to arrive by the first post on Monday or at latest be received not later than Tuesday morning

THE telephone number of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is Gerrard 2030 (Internal Exchange) The telegraphic addresses are

EDITOR of the BRITISH MEDICAL JOURNAL *Aitiology Westrand London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc) *Articulate West and London*

MEDICAL SECRETARY *Mediocracy Westrand London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street Dublin (telegrams *Bacillus Dublin* telephone 2337 Dublin) and of the Scottish Office 6 Putland Square Edinburgh (telegrams *Association Edinburgh* telephone 4561 Central)

QUERIES AND ANSWERS.

LONDON AMBULANCE SERVICE

V A C —A London horse ambulance service was organized by a voluntary association in 1882 It consisted of three one-horse vagons which were eventually handed over to the police authorities These vehicles which were in existence until the year 1909 were supplemented by 240 litters and 40 hand ambulances In the year the London County Council introduced a bill in the Parliament for powers to establish an ambulance service which was passed and received the Royal Assent in October of the year The service actually came into being in 1915 The Corporation of London had established a service in 1907 but this was confined to the City of London

AMBULANCE CARS

"TRANSPORT" has been asked by his committee to arrange some means of transport for patients to and from an isolation hospital in a very wide district, where the cases are not numerous He would be glad to receive suggestions from any fever hospital medical officer who has had a similar difficulty to meet He asks whether a trailer has been tried anywhere

*** We have consulted Major E W Paget, C B E, liaison officer of the Home Service Ambulance Committee of the Joint Council of the Order of St John and the British Red Cross Society (19, Berkeley Street, W 1) His reply is as follows "For isolation hospital work a small two stretcher ambulance on a chassis of the type used for light American touring cars has been found satisfactory The body should be coach built rather than of canvas, for ease of disinfection The cost of such a vehicle is about £200 to £250 Trailers were occasionally made during the war for ambulance work, but a self contained motor ambulance is now almost universally used" Major Paget is good enough to offer to supply our correspondent with further particulars if desired

INCOME TAX

Partnership Assessment

"R F P"—A and B are partners of equal standing, but entitled to different allowances for life assurance and in respect of children How should they divide the sum of £174 8s 7d which they have had to pay on their joint assessments?

*** Assuming that both receive life assurance allowances at the same rate, say 3s, the division should work out as follows

A's advantage	Life assurance	£30 at 3s	= £4 10 0
	Children's relief	£36 at 4s 6d	= 8 2 0
			£12 12 0
A's share		£80 18 4	
B's share	£12 12s + £80 18s 4d	= £3 10 3	
			£174 8 7

We are unable, however, to make this total agree with the figure quoted as the gross assessment, and we suggest that "R F P" might request the inspector of taxes to let him have a note setting out how the £174 8s 7d should be divided Such requests are, we believe, frequently made and granted

X ray Apparatus

"X RAY" installed an x ray apparatus in February, 1923, at a cost of £500 of which £40 was paid for plates, developing chemicals, etc, and £5 for insurance of x ray tube What deductions are due for income tax?

*** No allowance is due for the capital cost of purchase and installation, but deductions can be claimed for running costs and materials, also for insurance The depreciation allowance is not due because the apparatus is used in a "profession," but the cost of renewal is allowable as and when incurred The only deductions which "X Ray" can make at present therefore are (1) insurance £5, and (2) cost of materials, etc Strictly the latter should be restricted to the cost of materials, etc, used in 1923 but the inspector of taxes may agree as a matter of convenience to allow the lump sum of £40 and further similar expenditure as and when incurred These amounts will be professional expenses affecting the computation of the profit for the year to December 31st

LETTERS NOTES ETC

CHRISTMAS WEEK

OWING to the Christmas holidays we have had to send the current issue of the BRITISH MEDICAL JOURNAL to press on Monday instead of Wednesday This is always a difficult season for the production of a weekly journal, but when Christmas Day falls on a Thursday the dislocation of editorial and printing business is greater than usual—so much so that we can sympathize with the doctor who, when asked by his wife what he would like for a Christmas present, answered 'A Christmas past"

PROTEIN THERAPY IN GONORRHOEA

DR M W BROWDY (London W) writes I was pleased to note the remarks in the *Epitome of Current Medical Literature* for December 13th (No 469) on the finding of H E Ahlswede and W Busch that non specific protein is of such value in the treatment of gonorrhoea I described the method of treatment by injections of sterilized milk in the *Lancet*, April 27th, 1923, with satisfactory results, and since then have found this one of the greatest adjuvants in the treatment of gonorrhoea and its complications

HYOSCINE IN PARALYSIS AGITANS

"M D" a retired practitioner sends an account of a case of paralysis agitans in which great improvement followed the administration of hyoscine by the mouth The patient a male aged 62 had had the disease for seven years during which a considerable variety of treatment had been employed His face was mask like and florid, and his voice very feeble Great muscular wasting was present, his hands were cold and livid, and festination was marked The patellar reflex was feeble, and continuous tremors of the lower jaw, tongue hands, and legs were present These tremors often became violent, the patient could not sit down or rise from a chair, cross his leg over the knee or walk without his feet being placed by a nurse He could not feed himself, and the food tended to drop out of the mouth Hyoscine hydrobromide 1/200 of a grain was given, diluted with water, and another dose of 1/150 of a grain was given four days later Seven days after the first dose general improvement was noted, and two days later the third dose, 1/100 of a grain, was given Twelve days after the first dose the more violent tremors were absent, and the patient was generally better The dose was increased gradually up to 1/50 of a grain, steady improvement resulting Within a month of the commencement of the treatment the patient had regained complete control of his legs and could walk both forwards and backwards A week later he was able to rise from his chair and walk up and down stairs without help, a thing he had been unable to do for five years The treatment was continued, the dosage being varied as required The patient lived in comfort, and died eventually of bronchitis No untoward symptoms attended the use of hyoscine, which was the only remedy employed by our correspondent

BACKWARD DISPLACEMENT OF THE UTERUS

DR HELWOOD SMITH (Chichester) writes Dr Archibald Donald in his lecture (December 13th, p 1087) makes some observations not wholly favourable, on the treatment of cases of retroversion by pessaries In my practice at the Hospital for Women about forty five years ago we observed a large number of cases not only relieved but cured by the proper use of a pessary But then it must be proper, both in the method of replacement and in the pessary employed First the uterine sound should be passed with great care, the turn made, and, with the finger on the cervix, the uterus slowly placed in the normal position Then a proper pessary is introduced The usual Hodge is too flat, and many practitioners use too short a one, and so the uterus slips back into its abnormal position The proper Hodge is a Smith Hodge devised about the same time by Dr Albert Smith of America and myself In this pessary the upper portion is curved considerably forwards and the lower portion somewhat backward, so that when in position—and as long a one as can be comfortably borne is used—the uterus is kept in its forward position by the upper forward curved portion of the pessary, the lower portion being bent back, there is no inconvenient pressure on the urethra If the patient is instructed to use the douche carefully there is no need for frequent visits to the doctor, although she should be warned not to allow too long intervals to elapse, especially if any discomfort arises

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

DR J DICKINSON LEIGH, F R C S Ed (tuberculosis medical officer, Sunderland), writes From the recently published list of Fellows of the Royal College of Surgeons of Edinburgh I find that out of a total of about 1,800 there are 203 resident in Scotland as against 708 living in England I write to suggest the formation of an association of Fellows resident in England Much might be done in the way of raising funds to endow lectures to be delivered on the lines of those given at the sister college in London and also to throw open examinerships to men on this side of the border It is an encouraging sign to find that one examiner for the D P H has been appointed from England in the person of Dr Cookson Surely this appointment is unique

A TRIP TO TIMBUCTOO

To receive a circular endorsed by the familiar name of Thomas Cook and Son, giving times and fares of a trip to Timbuctoo makes the reader think that the earth must be shrinking as fast as, according to Professor Jeans, the sun The tourist goes by way of Marseilles and Algiers to rail head at Colomb Bechir, and thence by motor cars of the enterprising Citroen Company which provides them also with hotels or camps The motor trip from rail head to Gao takes eight days From Gao to Timbuctoo the journey (two days) is made by motor boat on the Niger It is not a poor man's holiday for the fare from Colomb Bechar to Timbuctoo and back is £475, and if the traveller steps off he pays £6 a day, but it must be interesting

WARMING THE ENGINE

MESSRS A W GAMAGE of Holborn, E C, sell a small lamp—the 'Warma" Radiator Lamp—for 14s 9d designed to protect motor car radiators from frost and to make engine starting easy on cold mornings The lamp is made on the principle of the safety lamp, the wick burning inside a cylinder of gauze Round the gauze cylinder is fitted a radiating muff of crinkled metal, said to have the effect of increasing the heat, but useful at all events for protecting the gauze from injury One filling of paraffin will keep the lamp burning for about forty hours The lamp is said to be quite safe so long as the gauze is uninjured, and such an accessory should be useful in protecting the cylinders and radiator from damage in a cold garage.

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 28, 29, and 31 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 30 and 31

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page xxx

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine

506. **Rickets**

E. J. WATSON and C. V. WEYMOUTH (*Journ. Amer. Med. Assoc.*, November 8th 1924, p. 1479) state that rickets is the most widespread infantile nutritional disorder of temperate climates. In a group of 400 babies, aged 3 to 8 months, in the out patient department of the Boston Children's Hospital skiagraphs and careful examination showed that 95 per cent. of all these babies and 100 per cent. of the Italian and negro babies had either active or healed rickets before the age of 8 months. During the winter all the babies showed some evidence of rickets; the rickety rosary was found the most trustworthy sign. Skiagrams in early cases proving unreliable. Since 1919 numerous observers have reported that ultra violet rays in doses approaching the limit of tolerance will cure rickets and tetany in the absence of any other treatment. In 1923 the authors organized a special clinic at the Boston Children's Hospital and during the last year 86 patients were treated with ultra violet rays three times in each week; six normal children used as controls, receiving the same treatment during a period of two months. Skiagrams of the wrists with palms upward were taken every ten or twelve days and the calcium and phosphorus in the blood plasma were estimated. The lamp was placed 20 inches from the skin surface, and the initial exposures continued for two minutes to the front and two minutes to the back of the body. These times were increased by one minute at each sitting, until a total of thirty minutes was reached. No undue erythema occurred even in the most delicate skins. No cod liver oil or medicine was given but an ordinary antirachitic diet was prescribed. All these 86 patients with acute rickets showed steady improvement and gained weight without change of food. The improvement was so definite that the parents willingly brought the children three times a week to the clinic, often from a considerable distance. Skiagrams showed increased calcium deposit at the end of two weeks but the improvement was much more marked when the longer exposures were being given. In all patients whose blood was examined before the commencement of treatment a low concentration of serum phosphorus was found and in those children who had both tetany and rickets there was also a low calcium figure. During the treatment both concentrations reached the normal in two weeks. Full details of 4 cases, with numerous skiagrams are given.

507. **Internal Secretions and Skin Diseases**

J. S. COVISA and J. BEJARANO (*Arch. de mal. cut. y esp.*, October 25th 1924, p. 149) state that proved cases indicating some relationship between diseases of the skin and endocrine changes are as rare as the hypotheses based on a supposed relationship are numerous. They maintain that the only instances in which a connexion has been definitely established between affections of the endocrine glands and dermatoses are as follows. In the first place in a large percentage of cases of acroasphyxia chilblains erythema induratum (Bazin) angiokeratoma (Mibelli) scrofuloderma and the other dermatoses which constitute the large group of tuberculides there is a more or less pronounced but almost always obvious condition of thyroid insufficiency which is manifested by a constant feeling of chilliness infiltration of the skin of the face, loss of hair etc. The most striking example of this group is illustrated by the skin changes in myxoedema. The authors have found that in many cases of tuberculides opotherapy has a very favourable action, as it shortens the course of the disease prevents the occurrence of secondary infections of the skin and causes a disappearance of the general symptoms of hypothyroidism which accompany these dermatoses. In the second place a relationship has been established between many changes in pigmentation, principally with states of suprarenal insufficiency and to a less extent with changes in the thyroid hypophysis and ovaries. Bahiña has shown that adrenaline causes a rapid disappearance of pigmentary syphilides which, as is well known are refractory to antisyphilitic treatment and sometimes remain unchanged for years. Lastly the authors say that there is an indisputable relationship between many cases of acne with changes in the thyroid especially increased activity of that gland. Their experience differs from that of Levi and Rothchild who found that acne was often associated with hypothyroidism.

508. **Extrocardia in Twins**

C. PEZZI and L. CALLIGARI (*Cuore e Circolazione*, October 1924, p. 361) record a probably unique case of cardio visceral transposition in twins who had reached the age of 25 years. There was no family history of heart disease. The father had died of gastric cancer at the age of 59 and the mother of pulmonary tuberculosis at 35. One sister aged 29 was in an asylum with dementia praecox while another sister aged 27 and a brother, aged 21, were alive and healthy. Before the war when the condition was first discovered, neither of the twins had had any illnesses worth mentioning. Both had taken part in the front line fighting. The condition was detected in one twin during an attack of malaria, when the liver dullness on the left was at first mistaken for splenic enlargement. Skiagrams in both cases showed that the heart was on the right side while the liver occupied the left hypochondrium and the stomach was on the right. Although it was impossible to affirm that the transposition of viscera was complete because the x rays could not demonstrate inversion of certain viscera such as the lungs, it was probable that the transposition involved other organs such as the intestine as was found by De Castro in two out of three cases. The electrocardiogram in the present authors' two cases was characteristic in each instance. In the first deflection the tracing was that of a normal subject but reversed, while in the second and third deflections the curves were normal—with this difference that he second deflection corresponded to the third of a normal subject and the third to the second. As regards the pathogenesis of transposition of viscera the authors accept the views of Martinotti and Lechte. Martinotti has shown that normally the left omphalo mesenteric vein is more developed than the right which disappears rapidly, and on this asymmetry depends the development of the organs especially the liver, stomach and spleen. Persistence of the right omphalo mesenteric vein and disappearance of the left produces transposition of the viscera and secondary rotation of the heart, though the latter is not inevitable like inversion of the abdominal viscera. Lechte attaches considerable importance to the umbilical veins, which are closely connected with the omphalo mesenteric veins and undergo a similar evolution, normally the left only persisting while the right disappears. On the other hand when the right umbilical vein persists, the omphalo mesenteric vein or future portal vein will pass to the left side of the foetus and the liver will develop in this situation the greater curvature of the stomach being found on the right.

Surgery

509. **Diverticula of the Bladder**

M. NEGRO and H. BIANE (*Journ. d'Urol.*, September, 1924, p. 217) from a study of thirteen cases of diverticula of the bladder draw the following conclusions. Diverticula are usually met with after 50 years of age though they are not rare in younger subjects, the authors report three cases occurring before this age. They are occasionally present in females two being found in women among the 8 cases. The diverticula are more commonly placed on the lateral walls of the bladder the size varies from that of a nut to that of a large orange. Two of the largest were discovered in patients of 24 and 32 years of age respectively. Multiple diverticula are more often found than single ones. The multiplicity appears to vary inversely with the size, for the large ones are usually single. Diverticula do not give rise to any special symptoms. The only pathognomonic sign appears to be micturition in two stages and this is found very occasionally. Other symptoms are cystitis and haematuria, and in one case there was *acute retention with acute unilateral pyelonephritis*. As regards complications there were two cases with calculi in the diverticula and one case with papilloma. The authors regard the cystoscope as essential in making the diagnosis. It gives information as to the number position, and location of the diverticula openings, but it is not always sufficient, and cysto-radiography is useful in these cases. By this means calculi in the diverticulum invisible by cystoscopy can be detected. As to treatment palliative means are said to be useless in getting rid of the infection or other complications present. The authors found surgical treatment only of any avail, and they describe the various procedures that have been adopted.

510 Spontaneous Gangrene of the Lower Extremities

F KAZDA (*Deut Zeit f Chir*, August, 1924, p 86) states that the causes of spontaneous gangrene have been classified by Israel as follows (1) Deficient supply of normal blood, as in arterio sclerosis and endarteritis obliterans, (2) normal supply of abnormal blood, as in gangrene of the extremities after infectious diseases, (3) deficient supply of abnormal blood, as in diabetic gangrene Apart from diabetic gangrene, Kazda distinguishes two forms of spontaneous gangrene The first form occurs in young or middle aged persons who are affected with more or less pure forms of angiospasm and endarteritis obliterans The prodromal symptoms, which often last for years, especially when both legs are affected, may be very violent Finally, the gangrene develops rapidly and involves segments of the peripheral parts of the extremities A segment of a toe, one or several toes, or a portion of the foot becomes discoloured, the pain being extremely severe The second form occurs in older persons with very pronounced arterio sclerosis Prodromal symptoms are absent or slight and of short duration The pain is much less severe than in the first form, the gangrene commences slowly, usually from an ulcer, and extends peripherally from it and not in a segmental manner The first form of gangrene is much the more frequent—Kazda saw 37 cases in men and 13 in women of the first form, as compared with 16 in men and 2 in women of the second form The average duration of the prodromal symptoms of the first form in men is one year and two months when one leg only is affected, and five years and two months when both legs are involved, and in women two years and eight months The duration of the prodromal symptoms in the second form never exceeds two months In the first group conservative treatment is always unsuccessful, and primary operation is required, whereas in the second group conservative treatment is indicated In diabetic gangrene conservative treatment should be attempted only in the mildest cases, which may be classified in the second group In all other cases amputation of the thigh should be performed, even if there is no coma Surgical measures should be accompanied by medical treatment of diabetes. The prognosis is always doubtful

511 Chronic Ethmoiditis and Asthma

HUMBLÉ (*Bruxelles Medical*, October 19th, 1924, p 1459) reports the case of a night watchman, aged 55, who had suffered from asthma and bronchitis for ten years or more After the removal of some nasal polypi some years ago he was temporarily relieved, but the attacks of asthma recurred, associated with severe bronchitis Humblé removed the nasal polypi with a cold snare, and also paid attention to some bad teeth and to the dyspepsia A few weeks later he proceeded to clear out the ethmoidal cells, having first ascertained that the sinuses were free from disease The removal of these cells gave complete relief, and the author suggests that the asthma was a spasmodic reflex due to the irritation of nerve filaments by the chronic ethmoiditis

512 Ascariasis and Acute Pancreatitis

W PFANNER (*Deut Zeit f Chir*, August, 1924, p 125) states that the increase of intestinal parasites during and after the war has frequently given rise to conditions requiring surgical interference Invasion of the bile ducts or liver by ascarides is a severe and dangerous disease, which becomes one of exceptional gravity when secondary changes in the pancreas ensue Pfanner records two fatal cases in men aged 44 and 54, in whom invasion of the bile ducts by round worms had not only caused the usual cholangitis, but had also led to severe acute suppurative pancreatitis The onset of the disease was not characteristic in either patient, but resembled that of other cases of ascariasis of the bile ducts, and the possibility of the invasion of the common bile duct or pancreatic ducts was not considered In the first case the possibility of cholecystitis with cholangitis was entertained, while in the second case the onset suggested gastric or duodenal perforation In the first case operation showed acute inflammation of the bile ducts, which contained extremely fetid bile infected with *B coli* In spite of cholecystectomy and drainage of the common bile duct signs of acute pancreatitis developed in a few days and death took place The pancreatic duct at the autopsy was much dilated and filled with an adult *Ascaris lumbricoides*, and multiple punctiform haemorrhages and areas of fat necrosis were found in the pancreas In the second case, in which death took place before operation, the autopsy showed early peritonitis and all the signs of acute pancreatitis A pair of ascarides was found in the common bile duct, with their heads towards the hepatic duct and their tails projecting from the papilla of Vater Twenty more fully developed ascarides were found in the stomach and duodenum

Therapeutics.

513 Caffeine in Epilepsy

P KARGER (*Deut med Woch*, November 7th, 1924, p 1531) states that he began to substitute stimulants for sedatives in the treatment of epilepsy with some scepticism, although the recent work of Stargardter had made out a plausible case for this change But the author's experience during the past three years with more than 60 cases has convinced him that caffeine may be remarkably effective in a considerable proportion of cases With the exception of ten patients, in whom the attacks were comparatively serious, his material consisted of patients suffering from petit mal, associated in most cases with enuresis In every case a definite connexion was established between the attacks, and tiredness and sleep At first caffeine was given only to those children in whom the attacks began on getting up or going to sleep, in the night, or towards the end of school hours The ages of the children ranged from 3 to 13 years, and, in order to eliminate suggestion as a factor in the treatment, tinctura amara was at first given for some days it had no effect Caffeine was then prescribed When the attacks used to occur in the morning only the caffeine was given before rising The dosage and the spacing of the doses were modified according to the requirements of the individual, it was found advisable to continue the treatment for two to three months after the symptoms had disappeared and to discontinue the treatment gradually No harm was done, and there were only three cases in which this treatment was ineffective In no case did the drug interfere with sleep, and in most cases the duration of the cure was considerable

514 Camphor in Bacteriaemia

E JARLOV (*Acta Med Scand*, Supplement VII, 1924, p 57) states that it has long been known that the growth of pneumococci is arrested in as dilute a solution of camphor as 1 in 10,000 Oil of camphor has been found unsuitable for subcutaneous injection because it is absorbed so slowly, and it is unsuited for intravenous injection because of the risk of fat embolism The investigations of Leo have shown that camphor is not so insoluble in water as it was thought to be, and, on Leo's prompting, the author has given intravenous injections of camphor in several cases of bacteriaemia Using a solution of 15 cg of camphor in 125 c cm of water, the author gave from 150 to 500 c cm or more to adults at one injection Each injection took from fifteen to twenty minutes, and in several cases one injection was given every day for a short period Among the numerous cases recorded by the author there was one of septic fever in a man, aged 21, who did not respond satisfactorily to injections of collargol On three successive days he was given 250 c cm of the solution of camphor, after the second injection the temperature fell to normal, and he was discharged from hospital much improved In a case of pneumonia, in a woman aged 29, the injection of as great a quantity as 400 c cm of the solution of camphor was immediately followed by a rigor, the temperature rising to 104° F, but she soon felt much better When, at a later date, 75 cg of camphor were injected in the course of about fifteen minutes, a rigor again developed, and the temperature rose to 103° F, a few hours later she felt perfectly well and she made a complete recovery In a case of severe puerperal sepsis as much as 90 cg of camphor was given in about fifteen minutes, and this dose was so large that the patient was rendered almost unconscious by it for a few seconds But neither in this nor in any other case did the injections inflict any permanent injury, and the author concludes that camphor, given in this way, is a very effective remedy for a great variety of blood infections He adds that it is not only a stimulant, promoting the functions of the vascular and respiratory systems, but it is also a powerful internal antiseptic

515 Atropine Sulphate in Acute Mania

A POPEA, L CONSTANTINESCO, and GIURGIU (*Bull et Mem. Soc Med des Hop de Bucarest*, September, 1924, p 188) have studied the vago sympathetic system in mental disease, with or without pathological lesions, using Daniélopolu's atropine test They have discovered that atropine sulphate has a specific action when injected intravenously in doses sufficiently large to paralyse the vagus, especially in cases of maniacal excitement When the dose was sufficient to accelerate the heart, and to produce mydriasis, maniacal patients became less talkative and excitable, they grew drowsy and more amenable to control In twenty cases, as soon as the test was completed, all the patients slept for three to eight hours, with the exception of two patients, who were drowsy but did not actually sleep, one other patient, a general paralytic suffering from maniacal excitement, was not calmed These patients awoke without the disturbance

that usually follows the administration of hypnotics especially of opiates, and the psychomotor disturbance was definitely less At the end of twenty four to forty eight hours the patients began to return to the maniacal state, but for many nights after the injection of atropine they slept naturally The authors consider that these facts appear to throw light on some obscure points in the pharmacodynamic action of atropine, and cite the following authorities Manquat states that atropine is not hypnotic in the usual sense It only produces sleep when given in massive doses, its action appearing to be the first stage of the coma which supervenes when a toxic dose is given According to Pauchet, however, it is a valuable soporific in disease, and Soulier reports that while belladonna stimulates normal nerve cells it calms those which are functionally deranged Furthermore, Radovici and Nicolesco have described a hypnotic action of atropine in patients suffering from epidemic encephalitis The present authors confirm that view, and show that the sedative and hypnotic effect of atropine corresponds with its paralysing action on the vagus The interdependence of these two effects has yet to be verified and it must be remembered that according to Tinel, Santenoise, and others, maniacal excitement is always preceded, if not produced, by a state of vagotonia If the two phenomena are connected the present authors think that the origin of conditions of excitement and especially of maniacal symptoms, may be due to hypertonia, or hyperexcitability of the pneumogastric which gives rise to attacks of maniacal excitement by cerebral irritation Sleep supervening after the calm produced by atropine would then be due to fatigue resulting from the previous excitement

Anaesthetics.

516. Local Anaesthesia in Cataract Operations

J MATHEWS ROBISON (*Arch of Ophthalmol*, November, 1924 p 570) describes in detail the various methods of anaesthetizing the nerves supplying the lids recommended by various authorities in connexion with cataract operations He has devised a technique of his own by repeated experiments The points which he particularly emphasizes are the necessity of paralysing not only the orbicularis oculi, but also the accessory muscles affecting the closure of the lids—namely the corrugator supercilii and the angular head of the quadratus labii superioris—and also the advisability of producing complete anaesthesia as well as paresis of the lids To ensure this latter it is necessary to block the supraorbital the supratrochlear and infratrochlear, the infraorbital, and the lacrymal nerves

517 Gas Oxygen Anaesthesia.

E I MCKESSON (*Journ Amer Med Assoc* November 8th 1924 p 1502) discusses the advantages gained by using pure gas oxygen anaesthesia in ear, nose, and throat surgery He points out that the coagulation time of the blood is shortened, and that under general pressure narcosis is made perfectly safe for patients with obstructive complications, such as quinsy or tumours Moreover, the danger of inspiration of pus blood, and infectious material appears to be diminished He has encountered no pulmonary abscesses, nor pneumonia as sequels, and no deaths He considers the sitting posture preferable for operations He reports difficulty in obtaining the abolition of the pharyngeal reflex unless morphine is also employed, and a second objection is the requirement of a special apparatus

518 Colonic Anaesthesia.

H W MEYER and B F ROBBINS (*Journ Amer Med Assoc*, November 15th, 1924 p 1581) sketch the history of colonic anaesthesia in a short preliminary note and then point out the indications for this form of narcosis as being (1) obesity (2) hyperthyroidism, and (3) operations about the head neck, and thorax Old age is not considered a contraindication, but intestinal disease, advanced nephritis and diabetes prohibit its use As in other forms of anaesthesia, the usual care before, during, and after induction must be exercised The colon is emptied forty eight hours before operation, and after twelve hours a soap and water enema is given About three to four hours before the operation a tap water enema is given, and an hour and a quarter before operation a suppository is introduced containing 10 grains of trichlor tertiary butyl alcohol and a hypodermic injection of 1/6 to 1/4 grain of morphine with atropine is given One hour before operation the ether oil mixture is introduced gradually into the rectum the rectal tube is left in position and is closed with a clamp Surgical anaesthesia may be expected after forty five minutes The standard formula used is ether 4 oz, paraldehyde 2 drachms and olive oil 2 oz If signs of danger appear during tube and pressure over the si are said to remedy the conditi rocedure includes colonic irrigation followed by a hot coffee enema, morphine should be withheld until the patient is fully awake The method is stated to be a very safe one, and to obviate post operative pneumonia after protracted operations

519 Resuscitation by Direct Cardiac Massage

W E LEES and T M DOWNES (*Annals of Surgery* October, 1924, p 505) call attention to the efficiency of cardiac massage in re establishing heart action after arrest during anaesthesia They emphasize the simplicity of the procedure and suggest that restorative measures are not exhausted until direct cardiac massage has been tried The number of recorded cases in which this has been successful is about 25 per cent They state that artificial respiration is most important in conjunction with cardiac massage, which must be started early, within two or three minutes of the cessation of the heart beat, after an interval of ten minutes it is seldom successful Time should not be wasted in hypodermic stimulation, which cannot act if the circulation has stopped The abdominal subdiaphragmatic method is usually employed, and is easy and quick Through an abdominal incision the heart is rhythmically squeezed against the chest wall If the heart is not restored to activity in two minutes the diaphragm should be incised and direct stimulation tried The authors consider that the intraventricular administration of adrenaline as advocated by Crile will be more certain and efficient in its action if combined with cardiac massage When the heart has ceased to beat it is doubtful whether anything except direct massage will restore its action

Obstetrics and Gynaecology.

520 Incontinence of Urine.

C J MILLER (*Amer Journ Gynecol and Obstet*, October, 1924, p 492) states that incontinence of urine is a common occurrence in women and usually follows injuries sustained at labour, though sphincteric weakness may be responsible in some nulliparous cases In 1 000 gynaecological cases collected by Taylor and Watt control of urine was found to be normal in 79 4 per cent and fair in 6 8 per cent, thus in 13 8 per cent there was poor control or incontinence Multiparity increased the frequency of incontinence, and 45 per cent of patients with prolapse were affected Miller considers that the cause is doubtful but is probably an injury of the vesico vaginal fascia which according to Taylor allows the inferior wall of the urethra to sag This tends to drag on the sphincter urethrae and to hold it open the sphincter itself is rarely injured In these patients the perineum is usually shallow and the anterior vaginal wall bulges on straining Many ingenious methods of treatment had been devised for this condition but failed owing to misconception of the cause of the incontinence The author remarks that modern methods consist in the tightening of the fascia around the vesical neck without attempting to narrow the sphincter, and that these have been eminently successful, especially when Clark's *U suture* was used to give immediate and later permanent support to the urethra and vesical neck An anterior colporrhaphy is required in nearly all cases to complete the readjustment of the whole fascial sheath In cases unsuited for operation he finds that pessary treatment, preferably the ring pessary has proved very efficacious, at any rate in the milder type of incontinence, for the weakened fascia is supported and sagging prevented

521 Operative Treatment of Carcinoma of the Uterus.

ACCORDING to an analysis by A GIPSI (*Ann di Ost e Ginecol* October 31st 1924 p 463) of the statistics of the Milan Obstetric and Gynaecological Institute the prognosis in carcinoma of the body of the uterus is less favourable than has recently been stated During the last four teen years 84 cases have been operated on 46 by the vaginal and 38 by the abdominal route the operative mortality being 2 7 per cent Those surviving patients whose after histories could be traced numbered 53 9 had recurrences within twelve months 8 during the second to the fifth years and one in the tenth year Twenty two patients were free from recurrence after five years 31 after two years The proportion of recurrences was 3 7 per cent, and of five year cures 41 5 per cent So far as statistics are concerned the operative mortality and incidence of recurrence were both less after vaginal than after abdominal hysterectomy but in this series those cases in which some degree of fixation of the uterus was perceptible clinically were chosen for abdominal operation The oldest patient was aged 69 The two youngest were 35 years old Judged by the operative and end results, carcinoma of the

body of the uterus does not appear to show any greater degree of malignancy in the younger than in the older patients In two cases the abdominal operation consisted in subtotal hysterectomy, one patient was lost sight of, but the other was alive and well eight years later It is not stated that the diagnosis was verified microscopically in all cases

522 Foetal Death and Protein Shock

E FISCHER (*Zentralbl f. Gynak*, October 4th, 1924, p 2203) has been accustomed to immunize pregnant patients suffering from any form of streptococcal infection In two cases of pyelitis of pregnancy this was followed by anaphylaxis In the first symptoms appeared in six days in the form of an exanthematous rash, most marked at the site of injection, and accompanied by swollen glands The rash became worse two days later, and the tonsils and larynx were affected Abdominal and joint pains then appeared, and were followed by labour pains Labour ran a very rapid course and was completed in four hours, although the patient was a primipara The child was born dead, petechial haemorrhages were found and an abnormally distended bladder In the second case the anaphylactic phenomena came on six days after the injection They were similar to those in the first case but not so severe They were followed by rapid onset of labour, which was completed in one and a half hours The patient was a multipara The child was born alive but feeble, and died in sixteen hours Marked internal haemorrhages were found, especially in the brain, kidneys, and suprarenals Fischer considers it probable that protein shock was the cause of death in these two cases and that it also accelerated labour unduly He has since then never given serum injections to pregnant women without taking precautions against anaphylaxis, or unless labour has already started, during the last ten months he has had no further cases of protein shock to report

Pathology.

523 Increasing Acquired Immunity in the Guinea-pig

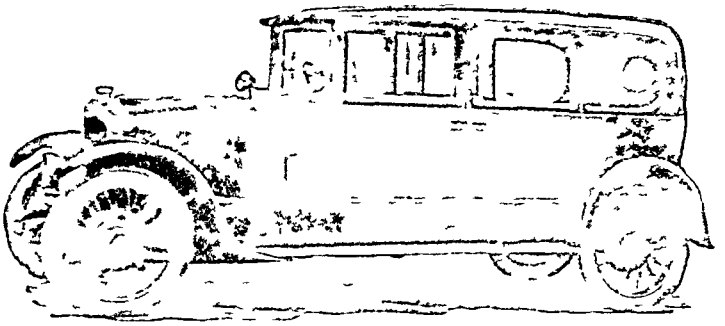
C ZOELLER (*C R Soc de Biologie*, October 24th, 1924, p 858) found that if guinea pigs were given two injections of diphtheria anatoxin they became, after a certain time, refractory to experimental infection with the diphtheria bacillus Inoculating the bacillus on the conjunctiva appeared to be devoid of effect, so far as symptoms were concerned, but on bacteriological investigation it was found that the bacillus had established itself in this position, thus converting the animal into a healthy carrier Wondering whether this establishment of the diphtheria bacillus on the healthy conjunctiva had any effect on the immunity of the animal, Zoeller carried out some experiments in which guinea pigs vaccinated with anatoxin and subsequently treated by conjunctival inoculation of living bacilli were compared with guinea pigs which had received the anatoxin only Into each animal three different dilutions of diphtheria toxin were injected intradermally, the dilutions employed were 1 in 5, 1 in 10, and 1 in 20 Whereas the first series of animals reacted to two of the dilutions and recovered, the second series reacted to all three dilutions and subsequently succumbed in a state of cachexia It appears, therefore, that infection with the diphtheria bacillus, subsequent to the establishment of immunity has a stimulating effect on the immunity of the animal, raising it to a higher level than that attained by the injection of anatoxin alone If this be true for man it is justifiable to suppose that the exposure of vaccinated individuals to infection in an epidemic medium would have the beneficial effect of increasing their immunity

524 Calcium Content of the Blood in Skin Diseases

H J SCHWARTZ and O L LEVIN (*Arch Derm and Syph*, November, 1914, p 544) found in over 300 cases of various diseases of the skin that no positive relationship between the blood calcium content and the disease appeared to exist, and there seemed to be no special significance in a decrease in the blood calcium unless marked In only one case of psoriasis was a definite decrease noted, but in acne, eczema, furunculosis, and folliculitis barbae several cases showed a noticeable decrease, and a decided improvement resulted in some from the internal administration of parathyroid and calcium lactate, such improvement being associated with an increase in the blood calcium Two cases of purpura and two of erythema multiforme gave low figures, but the number examined was too small to warrant conclusions, in urticaria there appears to be no deficiency

525 The Use of Arsenobenzene in Blood Transfusion

CH FLANDIN and A TZANCK (*Bull et Mem Soc Med des Hop de Paris*, November 13th, 1924, p 1487), while recognizing the excellent results obtained with sodium citrate in blood transfusion, believe that the arsenobenzenes have the following advantages (1) Anticoagulant power 0 03 to 0 06 gram of sulfarsenol is sufficient to render 100 c cm of human blood incoagulable, as contrasted with 0 3 to 0 5 gram of sodium citrate (2) Toxicity 0 01 gram of sodium citrate is a lethal dose, on intracardiac injection, for a guinea pig of 500 grams, while a similar guinea pig will survive a dose of 0 03 and even 0 05 gram of sulfarsenol In man the toxicity of the amount of sulfarsenol used in transfusion is *nil*, save in exceptional cases (3) Blood changes The action of the arsenobenzenes on the blood seems analogous to that of sodium citrate Anticoagulant action is not due to the destruction of globulins Complement disappears immediately on the addition of either of these, so that the original Wassermann test is impossible with blood so treated Poikilocytes do not appear so quickly after the addition of sulfarsenol as after sodium citrate (4) Dilution of blood By using sulfarsenol it is only necessary to add a trace of foreign liquid to the blood, while sodium citrate involves the addition of a much larger bulk of fluid.



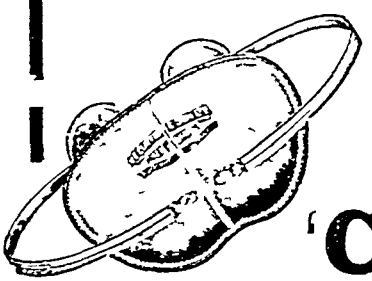
526 Production of Tuberculous Cavities in the Rabbit

A PHILIBERT and F CORDEY (*C R Soc de Biologie*, November 21st, 1924, p 1072), in their experiments on reinfection in tuberculosis, instead of using the guinea pig as most workers have done, chose the rabbit Large doses of tubercle bacilli —type not stated—were injected intratracheally (1) into animals which had been previously infected by subcutaneous injection, and (2) into animals which had been previously infected by intratracheal injection Whereas in the first class the pulmonary lesions following reinfection were diffuse, hyperplastic, and showed no tendency to caseation, in the second class nodular caseous lesions were formed which broke down with the production of large cavities The first injection consisted of 50 mg of bacilli, the second, given one or two months later, of either 1 mg, 50 mg, or 100 mg The rabbits which received 1 mg showed at autopsy large caseous foci, which did not soften and break down, those which received 50 mg showed in two cases out of five large caseous foci, some of which were softened and others of which were on the point of breaking down and discharging, those which received 100 mg showed enormous cavities In the case of one animal which received a preliminary dose of 50 mg, followed a month and a half later by a dose of 100 mg, the autopsy, performed five days after the reinfecting dose, revealed a large cavity, the size of a nut, in the left lung, and a large cavity, the size of a small nut, at the summit of the right lung These experiments show, according to the authors, that infection and reinfection by the tracheal route do not give rise to an allergic reaction with congestion and focal necrosis, but to massive caseation The first infection did not protect the animal against reinfection

527 Conversion of Saprophytic Acid-fast Bacilli into Tubercle Bacilli

A CALMETTE (*Rev Belge de la Tuberculose*, October, 1924, p 293) gives a critical summary of the literature relating to the possible conversion of saprophytic acid fast bacilli into pathogenic tubercle bacilli and the reverse transformation, adding a few experiments of his own Though he has been able to induce certain alterations in the virulence of the tubercle bacillus, he has never succeeded in bringing about a change of such a degree as to justify him in considering it of significance in so far as this question is concerned By cultivating tubercle bacilli on glycerin bile potato for a period of thirteen years he has produced a bacillus which, though still acid fast, has lost all its virulence, and is unable to give rise to tubercles in any species of animal Yet its power of producing tuberculin remains as strong as that of the normal tubercle bacillus, and on injection into animals it gives rise to antibodies which can be titrated by means of the complement fixation test, using an extract of the tubercle bacillus as the antigen Similarly, in the literature, he is unable to find any evidence of value pointing to a conversion of the tubercle bacillus into a saprophytic form With regard to the reverse transformation—the conversion of the saprophytic acid fast bacilli into pathogenic tubercle bacilli—the evidence is equally defective, according to him Experiments he has made with the Timothy grass bacillus have shown a complete lack of adaptation of the organism to a parasitic existence He concludes, therefore, that mankind has nothing to fear from the saprophytic acid fast bacilli.

Built for the Doctor's Comfort.



Complete Cars from £475

If the severity of the Winter has brought you to the conclusion that you MUST change your Car then let the experiences of your Colleagues decide the issue Buy a De Dion IT IS A DOCTORS CAR, built to withstand the storms of winter and the ravages of time You may neglect it and it will still render exceptional service, but give it a reasonable amount of attention and it will yield the boon of everlasting comfort and the unfailing day by day service that a Doctor so much needs

X RAYS for General Practice

¶ X RAYS offer a most important addition to a General Practitioner's service, the value of which it is impossible to compute.

The

'General Practice' X-RAY APPARATUS

is the latest production of the Medical Supply Association Automatically safeguarding against those scientific and technical difficulties previously met by the inexperienced it is expressly prepared for the service of the General Practitioner, and by its means he is enabled to produce valuable radiograms with ease and efficiency

"You switch on, we do the rest."

Price Complete

For Alternating Current £185 0 0

„ Continuous „ £230 0 0

Extra for latest modification to enable the X Ray Tube to be used from beneath the couch upwards as well as from above the couch downwards thereby making the apparatus universal in its application Extra **£18 10 0**

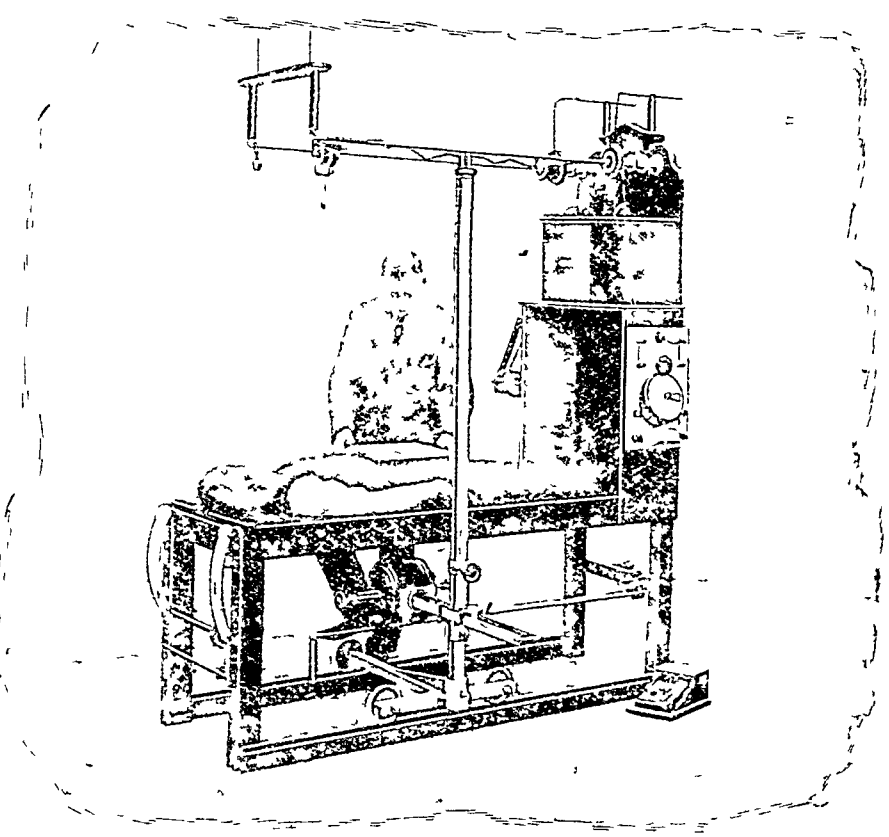
NOTE —The above price is for the complete installation, inclusive of accessories viz —

High Teasion Transformer Filament Heating Transformer Filament Control Coolidge X Ray Tube Oak Cabinet for supporting apparatus Radiological couch vertical screening stand marble switchboard x ray tube stand for radio therapy and dental radiography Foot switch for remote control fluorescent screen with protective lead glass front intensifying screens intensifying screen casette photographic tank development outfit dark room photographic lamp radiographic compressor Anti Corona high tension overhead conductors illuminated negative viewing box PATENTED TECHNIQUE DIRECTOR FOR INDICATING THE IDEAL FACTORS FOR RADIOGRAPHING ANY PART OF THE HUMAN BODY WHICH ENABLES ANYONE TO USE THE APPARATUS EVEN THOUGH THEY HAVE HAD NO PREVIOUS EXPERIENCE IN RADIOGRAPHY

mean Accuracy of Diagnosis as well as Increased Remuneration

¶ There is no substitute for the X Rays

¶ A scientific and congenial service with a good remuneration



¶ RADIOGRAPHY BY THE NEW "Technique Director" process is now so simple that any Doctor can use it

¶ *Call and see the apparatus at work Continuous daily demonstration, or send for Catalogue No 22 B fully descriptive*

I enclose cheque in settlement of my account I have adjusted the rails for trolley as you suggested and they are now entirely satisfactory

"The high quality of the radiograms I am obtaining exceeds my highest expectations and I can unhesitatingly recommend the apparatus to any surgeon who has to, or prefers to do his own X Ray work —Yours faithfully,

"————, M D , M S Lond , F R C S Eng"
